You are a nithing- homo sapiens by birth, subhuman BY CHOICE. The
key word is CHOICE. You were born with the same human nature as the
rest of us. Your CHOICES made you a nithing.

Bill explains what nithings are.

http://www.israpundit.com/2008/?p=3D9446

Define and Dehumanize the Enemy: Jihadists as Nithings or Nidings

by Bill Levinson
It is an ancient principle of magic (which modern people recognize as
stories that reflect a society=92s culture and psychology) that
knowledge of a person=92s real or True Name delivers power over that
person. What it really means is that, if you know the person=92s
psychology, you can gain an advantage over him. It is also well known
that the side that controls the language of an argument controls the
argument. As an example, Hamas terrorists and their enablers refer to
Israel=92s military as an =93occupation force=94 and terrorisitic violence
against civilians as =93resistance.=94

We have long sought a single word that strips the enemy of all
humanity, and reduces him to something less than an animal that is
worthy of nothing less than extermination. As far as we know, the
English language contains no such word, although =93dreck=94 (garbage or
refuse) comes close. =93Homo sapiens by BIRTH, subhuman by CHOICE=94
describes Islamic supremacists perfectly, but it is a phrase and not a
word. We now propose to refer to Islamic supremacists as nithings or
nidings: a Scandinavian word that strips its object of all humanity.
Webster=92s dictionary (1913) defines it as =93A coward; a dastard; =97 a
term of utmost opprobrium.=94

We remind readers who object to the dehumanization of Islamic
supremacists that those enemies are already attempting to dehumanize
Jews, and to a lesser degree Christians, with images that could have
come directly from Adolf Hitler. As they have chosen to sow the
dragon=92s teeth, our position is that they must now reap their rightful
harvest: the complete hatred and loathing of all civilized human
beings.
nithings

Nithing or niding was more than a common insult, because Scandinavian
culture required its subject to fight a duel with the accuser or
become an outlaw: totally devoid of rights, honor, and even

recognition as a human being. Per the Wikipedia entry,

The actual meaning of the adjective argr or ragr [=3D Anglo-Saxon earg] was the nature or appearance of effeminacy, especially by obscene acts. Argr was the worst, most derogatory swearword of all known to the Norse language. According to Icelandic law, the accused was expected to kill the accuser at once. =85If the accused did not retort by violent attack yielding either the accuser to take his words back or the accuser=92s death, he was hence proven to be a weak and cowardly nithing by not retorting accordingly.

A nithing was devoid of all human rights, and he was considered the enemy of civilized humanity: a perfect depiction of Islamic supremacists. The word therefore strips the enemy of all humanity, and degrades him to the status of a wolf or strangler (per Scandinavian tradition) or a virulent disease like the Black Plague. Black Plague is a deadly and contagious disease whose vector consists of plague-carrying rats, while the Green Plague of militant =93Islam=94 is a deadly and contagious ideology that is spread by bipedal rats: nidings or nithings, non-humans that raise violent hands to all of civilized Humanity.

The immediate consequence of being proven a nithing was outlawing. The outlawed did not have any rights, he was exlex (Latin for =93outside of the legal system=94), in Anglo-Saxon utlah, Middle Low German uutlagh, Old Norse utlagr. Just as feud yielded enmity among kinships, outlawry yielded enmity of all humanity.[63] =85=94Yet that is but one aspect of outlawry. The outlaw is not only expelled from the kinship, he is also regarded henceforth as an enemy to mankind.=94

The actual definition of a nithing is somewhat more involved and complex, and it gets into sexual perversions and zoomorphical transformations (Loki=92s transformation of himself into a mare to have sexual intercourse with a stallion, and thus beget Odin=92s horse Sleipner is probably an example), but the following line is pertinent: =93The nithing used its malicious seid magic to destroy anything owned and made by man, ultimately the human race and Midgard itself[6], due to its basically unlimited envy, hate, and malice that were nith.=94

=93Destruction of everything owned and made by Man=94 (the Palestinians=92 destruction of the greenhouses in Gaza comes to mind immediately) and =93unlimited envy, hate, and malice=94 describe militant =93Islam=94 perfectly, and further underscore the application of nithing or niding to describe it. The propensity for mindless destruction also appears in Orson Scott Card=92s Alvin Maker series, in which a supernatural enemy is known as the Unmaker: a personification of evil that is the total antithesis of God the Creator.

The Unmaker is the main antagonist in Orson Scott Card=92s alternate history/fantasy series The Tales of Alvin Maker. Never directly confronted, it is a supernatural force that breaks apart matter and aims to destroy and consume everything and everyone. =85To make something is to oppose the Unmaker, but a point often made is that this is futile. By natural law the Unmaker can tear down faster than any man can build.

This also is an outstanding definition of militant =93Islam=94 or Islamic supremacy: an ideology that seeks to destroy everything into which it comes in contact, and with which no reason, negotiation, or compromise is possible.

In summary, a nithing or niding is the enemy of Civilization, a subhuman (through its behavioral choices, and emphatically NOT due to its racial or ethnic origin) monster with total hatred and malice toward all human industry and arts, and worthy of nothing but extermination like any virulent disease. This is the word we will now apply to Islamic supremacists and their enablers, and we encourage others to do likewise.

You are asking me, what would Hitler have accepted besides the worst
possible outcome?  Is it really just because of a misunderstanding of
English that the world suffers today?

Have you ever heard the Grateful Dead lyric, "A friend of the devil is a friend of mine?" It has to do with accepting the enemy of an enemy as a friend, or perhaps at least an accomplice.

Michael JONES often congratulates Anders Breivik for massacring people in Norway. His reason for supporting Breivik is that he said that all of the people eliminated were Islamic Sleepers. What these are are people who are secretly followers of Islam, being trained to subvertly infiltrate Christian and Jewish society in order to destroy them.

You condemn Jihadists (Islamic Supremacists) as "nithings," supposedly the worst thing there is.

Then you call Michael JONES a nithing. Michael JONES calls you a satanic nazi.

So, you hate Michael JONES, Michael JONES hates you, and both of you hate Islamic Supremacists.

Since you have something in common, can't you find a way to get along?

the subject. TIA Jimmie

OK, the best info I got was to play with a few cable samples and test equip=
ment like I was going to use before building the cable. See how phase chang=
es responds to trimming. There doesnt seem to be as much "magic" and "art" =
to it as some have claimed. Heliax with compression fittings make the job e=
asy.

Jimmie

Yes, now that you mention it, I recall that this sort of thing is
frowned upon. However, the occasional off-the-cuff comment gets through.

I will rewrite this piece and have it on your desk by Monday.

I sense doubt that the resolution of WWII caused the world to suffer.
What happened there was like a mother saying to her child, "Stop crying
or I will spank you some more."  This was the new world policy.  I am
not a parent, so I cannot say for certain whether this tactic works or
not, but it seems counter-intuitive to me.

Here's Tom with the numbers on whether any countries have died out since
'45.  We will blame them all on this policy.

I do not ever recall seeing it, but maybe two 'ugly baluns" could be used.
One with say 10 turns (or what ever) and then a few feet away another with
20 turns. One would be good for say 3 to 15 mhz and the other good for 15
to 30 mhz.

However by the time you use this much coax, the bead type choke may be
cheaper.

An interesting thought. I have not read anything that discussed it
before.
Perhaps both the W2DX choke and the ugly balun?

Or may be one is really enough?

Summary: Recruitment announcement for ham-radio-related FAQ articles
Keywords: FAQ, Intro, amateur, ham, radio, recruit, recruitment
Bytes: 3549

Posted-By: auto-faq 3.3.2 beta (PGPMoose V2.0, Perl 5.005)
Archive-name: radio/ham-radio/recruitment
Revision: 1.2 2009/11/25 14:41:01
Posting-Frequency: posted twice monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been recently revived by an active moderation team. We are currently seeking suitable information, FAQ, and bulletin articles from the entire rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our newsgroup.

We are seeking a replacement maintainer for the following information bulletin formerly posted to rec.radio.amateur.* (and currently archived at http://www.faqs.org/faqs/radio/personal-intro/):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

One significant omission, requiring immediate updates, for this article |
is that it does not mention newer amateur radio newsgroups created since |
it was written, including: |

rec.radio.amateur.antenna |
rec.radio.amateur.boatanchors |
rec.radio.amateur.dx |
rec.radio.amateur.equipment |
rec.radio.amateur.homebrew |
rec.radio.amateur.moderated |
rec.radio.amateur.space |

We are willing to provide any technical support necessary to get this article updated and automatically posted again at a regular interval. This would include establishing contact with the original maintainer for any necessary permissions. We would prefer to seek a new, dedicated maintainer at this time, rather than start auto-posting the original article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to
rec-radio-info-request@panix.com.

Hi

Does the Shakespear or standard marine antenna base that is 1" 14tpi fit anything else?

What about 1" national fine thread hex bolt? Or 3/4" npt plumbing type thread? Anyone have any luck using something else without ruining the threads? I cannot use one of their oem swivel base things for the application I thinking of doing.

thnx for any advice,

73s

Rick-

Jeff and others have probably answered your questions with regard to antenna design. I was wondering what your WWVB receiver was to be used for?

I considered such a receiver, as well as amplifying WWV at other frequencies. My goal was to derive an accurate frequency to be used for calibration of counter timebases.

What I settled on was a Rubidium Controlled Oscillator. I found an Efratom (Ball) unit on E-Bay, that generates an accurate 10 MHz. I had to build a 24 Volt power supply for it. It is probably accurate within a few parts per billion, and is not affected by propagation or interference.

Yes, some farm impliments that I blundered across in the 1970's.
1"-14 UNS (class 2a and 2b) are used only for marine mounts. UNS
means "Unified National Special" which makes it a defacto standard
thread.

>What about 1" national fine thread hex bolt? Or 3/4" npt plumbing type
>thread?

Did you perhaps notice that the 1"-14 UNS thread is a straight thread,
while all the NPT plumbing threads are tapered?

>Anyone have any luck using something else without ruining the
>threads? I cannot use one of their oem swivel base things for the
>application I thinking of doing.

I'll do everyone a favor and not describe some of the antenna mounting abortions that I've seen in the Moss Landing and SCZ harbors, and at a former employer in the marine biz. Let's just say that it can be made to fit a variety of non-standard mounts, in a wide variety of ways, most of really disgusting.

>thnx for any advice,

So, what are you trying to accomplish?

I wasn't sure if the threads were straight as the bolt or tapered as npt (national pipe taper).

I was trying to avoid buying the actual proper thread base (OEM), thought a pipe nipple would work but it didn't, thought a bolt would work but it didn't.

So was wondering if the threads were chewed and that was the reason it wasn't working. I don't have that size tap anyway. Mabey a pipe tap but not a 1" national fine thread straight tap.

Wanted to make a base but now see they are only 20 bucks on fleabay

What would be the best antenna for 2m one could fit up within the 8ft fiberglass shell? That simple cutting of the coax can't be the best can it? This new fiberglass whip I just got is one of the good old ones, very solid and not flaky or nothing like the new shakespear ones they are producing. My cover breaks those too easy.

Plenty more to choose from:
<www.ebay.com/sch/i.html?_nkw=marine+antenna+mount>

>What would be the best antenna for 2m one could fit up within the 8ft fiberglass shell?

What's a "shell"? I'm visualizing a giant fiberglass clam shell. Very marine looking, but not your typical vessel. Can you be a bit more specific?

Does 2m mean 144-148MHz ham radio, or a 6ft marine fiberglass antenna?

>That simple cutting of the coax can't be the best can it?

I don't understand. That "best" at doing what?

>This new fiberglass whip I just got is one of the good old ones, very solid and not flaky or nothing like the new shakespear ones they are producing. My cover breaks those too easy.

First a "shell", than an ambiguous use of 2meters, followed by a vague "best", and now a "cover". Perhaps you've had an overdose of election year rhetoric and are trying to emulate the politicians by being vague. Hopefully, it's not contageous. Some clarification would be helpful.

If you look inside the older (1970') 3ft and 6ft fiberglass whips, you'll get an interesting surprise. Most of the antenna is sticky back copper tape, about 1/4" wide, and glued to the inside of the fiberglass taper. The fatter antennas are usually better built out of

copper plated welding rod. The best are stainless rod. The problem
is you can't really tell unless you tear it apart.

How to mount a 2.4GHz omni on a 1"-14 marine antenna mount:
<http://802.11junk.com/jeffl/antennas/marine-omni/index.html>

Hi Fred,

I am building the antenna as part of a radio controlled clock whose purpose is to construct it to use as little power as possible. This will be powered from scavenged sources such as thermal differences, pressure variations, vibration, light, etc. So the receiver will be done in a very low power FPGA using minimal circuitry and as little analog circuitry as possible.

I may create a PLL to track the phase of the signal. This would use a tunable crystal oscillator which would be "conditioned" against the WWVB signal over long periods of time.

I'm not specifically looking for a reference source, but this would be capable of providing one.

Rick

The thread is Straight Cut as opposed to NPT, which is Tapered...
HOWEVER,

I have cut 3/4" NPT Threads, using my Pipe Threader, that will work on Marine Antennas. The trick is to have an Adjustable Die, and cut the threads just a tad bit deeper than normal 3/4" NPT. It works well, as long as your Pipe has enough wall thickness, to take the deeper threading. I have used in in Alaska for years, and had no issues with the antennas or mounts.

That sorta works because 3/4" NPT is also 14 TPI (threads per inch). Also, pipe is measured by the inside diameter, while nut and bolt type hardware, which includes 1"-14 antennas, is measured by the outside diameter. The result is that 3/4" NPT and 1"-14 UNS can be made to fit.

I've seen the results of this method of antenna mounting. If the antenna base is heavy and strong, it will work. If it's cheap pot metal, the tapered pipe thread will crack the base when tightened. If the 3/4" NPT is a little on the large side, it will be supported by only by one or two threads. Hit the antenna with anything, and the base will peel out of the mount.

The practice of using 3/4" NPT mounting is even more of a problem with

GPS antennas, which are usually mounted on some manner of pipe. In order to avoid having two thread standards, Trimble and other have standardized on an odd compromise threading that works with both 1"-14 and 3/4" NPT. For example:
<http://trl.trimble.com/docushare/dsweb/Get/Document-8420/Bullet-III_DS.pdf>

> The socket accepts either a 1"-14 straight thread (typical marine antenna mount) or a 3/4" pipe thread.

However, to the best of my knowledge, such a thread is not used in marine antennas.

You really stuck your foot into this one Bruce, now you are going to be stuck answering stupid questions for the next couple of weeks.

The Fiberglass Shell as the OP called it is called a Radome.

http://en.wikipedia.org/wiki/Radome

The problem the OP has - besides being cheap and wanting something for nothing is the fact that he does not understand what is inside of the radome.

If you disassemble and Antron A99 or a Diamond X 500 - once inside, you will find a piece of copper wire or steel wire or stainless steel wire that is usually copper plated.
Between each section - spaced for certain wavelengths is capacitors of unknown origin which makes the antenna into segments - some for 2 meters and some for 70 CM.
This is what gives it its gain.
These are purpose built antenna's for those frequencies..

You cannot take a Marine antenna - that uses a different frequency and use it on amateur frequencies - due to the fact that there is no way to get internally inside of the antenna and change the lengths of the segments of the wires inside of the antenna.

Unfortunately - there is not a lot of educated Elmers out there that are willing to help a newbe - just due to the fact that most of the people who are left in Amateur Radio came from the CB radio and they were not knowledgeable - like the ones who came before them.

Most of them never built anything in their life and are just appliance operators.

I believe I had this conversation with this person or another person like this person previously.. My advice was that if the threads are of a ******* Origin and you are not willing to repair them or buy the mount to throw away the antenna..

They do not make a tap and die or make one that is economically feasable to repair a $10.00 antenna..   When you get into non standard threads - if you can find a tap and die - they tend to be quite pricey..

We are talking $60 - $100 each...

You would have to fix a whole bunch of antenna's just to break even, and it wouldn't be economical to buy it to fix one antenna.
You could buy a Diamond X 510 for about $150.00 and it would be already designed for the frequencys you desire to operate on.

Hmm...$780? I don't think so, LOL.

"BDWS-65n 4 - 54 Mhz Folded Dipole, Stainless Steel, 65 Ft, N connector,
1 KW"

How can they ask $780 for this antenna? Am I missing something? I can't imagine this would outperform my loop, especially on the low bands.

Thanks for the recommendation, though.

So much for diplomacy.

>If you disassemble and Antron A99 or a Diamond X 500 -

$270 list for the Diamond X-510.
<http://www.rfparts.com/diamond/x510series.html>
The problem with such large antennas for VHF use on a vessel is that they have too much gain. The vertical radiation angle is fairly narrow. My guess(tm) is about 5 degrees at 450MHz and 10 degrees at 146MHz. As the vessels pitches and rolls, much of the RF is directed into the water or into the sky, with very little going towards the horizon. Unless one has a gyro stabilized platform, a lower gain antenna might be more useful.

>once inside, you
>will find a piece of copper wire or steel wire or stainless steel wire
>that is usually copper plated.

Inside a Diamond X50 dual band ham antenna.
<http://802.11junk.com/jeffl/antennas/Misc/x50.jpg>
Sorry about the lousy photo. It's badly stitched together from four seperate photos. If you're wondering what happened, the former owner leaned the antenna against the garage wall, and then backed his car into it.

>Between each section - spaced for certain wavelengths is capacitors of
>unknown origin which makes the antenna into segments - some for 2 meters
>and some for 70 CM.
>This is what gives it its gain.

That's the brass sleeve section in the middle. The gain is provided mostly by properly phasing the radiating sections so that the signals add.

>These are purpose built antenna's for those frequencies..

I should hope so. I would be seriously worried if they were built without any purpose in mind. Perhaps for decorations as it's well known that the uglier the antenna, the better it works.

>You cannot take a Marine antenna - that uses a different frequency and
>use it on amateur frequencies - due to the fact that there is no way to
>get internally inside of the antenna and change the lengths of the
>segments of the wires inside of the antenna.

You'll be amazed at how little is actually inside a marine antenna. I don't have any photos handy. Most are copper tape glued to the inside of the tube, errr... radome. The rest are variations on coaxial (sleeve) antennas. However, for entertainment, I glued some magnetic recording tape (ferrite) along the copper tape and was able to lower the resonant frequency from about 156MHz to about 149MHz. That's not enough for ham use, but does show that it can be done.

>Most of them never built anything in their life and are just appliance
>operators.

Again the diplomacy problem...

>They do not make a tap and die or make one that is economically feasable
>to repair a $10.00 antenna..   When you get into non standard threads -
>if you can find a tap and die - they tend to be quite pricey..
>We are talking $60 - $100 each...

<http://www.ebay.com/itm/380414359502> $29
However, the dies are rather pricy.

Thanks Channel Jumper

I don't think my questions are "stupid".

First off, you didn't answer my last question, you sounded pretty intelligent with your swaying me thoroughly into oblivia, completely around my question.

It is obvious you understood the question, probably knew the answer, but didn't answer my question. Remember Channel Jumper, radio wave propagation and antenna theory was not what I majored in at the schools. I did graduate you know. I mean a accredited university gave me my masters. Do you have any accredation at all? Well then you cannot call me "stupid". I am willing to bet my career required a lot more years of study than yours. And continuous learning and upgrading. Yes, you are very knowledgable in regards to antenna work, however follow me for a day and I am sure you would be asking a lot of "stupid" questions.

I will ignore negative comments from you. But you still didn't answer my last question, you brilliantly jigged right around it. Wouldn't touch it. I figured you didn't know the answer yet it was on topic, about the coils of the dipole, but you went right around it twice. Why not just say you don't know the specific answer? Instead of trying to thrill me with your wealth of knowledge on antenna design and engineering, I just wanted to know lengths and widths. But you read a page from your first year electrical theory course to me that went right around my question.

Channel Jumper may be a real smart Book Learned Radio Guru..... but he
doesn't know squat about Marine Antennas, and how well they work, on the
2 Meter Ham Band. Having spend a career in Marine Electronics on the
West Coast, and Alaska, I can state with 100% certainty, that a Marine
VHF Antenna, will certainly work, on 2 Meters, with very little
degradation, and about 90% of Radio Horizon to Radio Horizon coverage,
when the TX Power RF Output level is above 25 Watts. I have considerable
experience with designing, and installing, VHF Paths for Control & Comms
for the Fishing Industry, and Marine Coast Stations, all over the West
Coast and Alaska. I used 2 Meters to pioneer those paths, with Marine &
Business Antennas, before the appropriate Licenses were issued, for use
on the Marine and Business Frequencies. Never had a significant change
in Path Fade margins, or Path Loss Data, between the Pioneering
Frequencies, and the Final Operational Frequencies. Just Say'en....

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35f23326

the rec.radio.amateur.moderated Moderation Team had decided to consider |
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. After a successful trial |
period (90 days, through early July 2009), we decided to adopt this |
change permanently. |

Approved rec.radio.amateur.* newsgroups are those that are currently listed in the latest version of the "List of Big Eight Newsgroups" which is crossposted monthly to news.announce.newgroups, news.groups, and news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those that have been created consistent with the suggestions in "So You Want to Create an Alt Newsgroup" at:

  http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either "radio.amateur" or "ham-radio" in their names, including uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved newsgroups up-to-date. In case we have overlooked any, and a submission is rejected in error as a result, the rejected submitter can E-mail us at our administrative contact address (in the signature at the bottom of this article, and the default Reply-To for the rejection message) requesting that it be added, and that the article be approved. We may still choose to reject articles crossposted to any alt.* newsgroup with an inappropriate name, including obscene language, embedded name-calling, or encouragement of unlawful conduct.

Please direct any comments, questions, or criticisms to rec-radio-amateur-moderated-request@panix.com.

Put the antenna on a terminated wattmeter and see how little power you actually couple in this manner. Incidentally, this is also why through the glass antennas are lossy. Such coupling arrangements were popular with cell phones that lacked a proper external antenna connector. They function acceptably only in strong signal areas, but still are rather lossy. I had one in the car kit for my Motorola MicroTac Flip-Phone.

I can't tell from your miniature photo what model commerical VHF handheld you're using. If it's Motorola, there are a variety of bizarre and often complicated antenna adapters for literally all their handhelds. Same with Kenwood and other handhelds. I have a fair size collection. For example:
<http://store03.prostores.com/servlet/henryradio/the-181/BNC-Antenna-Adapter-/Detail>
<http://store03.prostores.com/servlet/henryradio/the-122/BNC-Antenna-Adapter-for/Detail>
<http://store03.prostores.com/servlet/henryradio/the-251/BNC-Antenna-Adapter-/Detail>
<http://store03.prostores.com/servlet/henryradio/the-90/BNC-Antenna-Adapter-/Detail>
etc. One of these adapters is required to connect the radio to a service monitor for bench testing.

Through the glass antennas have at least -3dB loss.

read the specs.

Hi OM Jeff,

Thank you very much for all the information.

The rig in the photo is a Kenwood with a BNC!

The problem was with a Motorola HT.

73

Nandu.

I would be interested to know how they get 2dBi gain from a monopole with a ground plane, ground radials, or 1/4 wave sleeve for decoupling. Bandwidth, VSWR plot, install instructions, power handling limit, etc seem to be lacking.

I've done measurements and reverse engineering on several commercial through the glass antennas. For loss testing, I removed the antenna rod, found a suitable grounding point inside the base, attached a coax pigtail, and connected it to a spectrum analyzer for sweep testing in the cellular phone and PCS bands. The best I saw from about 4 different devices was about 4dB loss. The remaining RF was either dissipated in the glass, reflected as VSWR, or radiated through the glass gap.

These daze, automobile glass is coated with one of a variety of coatings designed to prevent the vehicle from becoming an oven. TiN (titanium nitride) seems to be the most popular (not sure). The problem is that with a sheet resistance of about 35 ohms per square, TiN does as good a job of blocking RF as it does blocking IR. To allow cell phones to be used inside the vehicle, the side windows are usually not coated. Although I've never seen it, applying RF to a through the glass antenna on a TiN coated window might cause the TiN coating to "blister".
<http://802.11junk.com/jeffl/crud/Low-E-titanium-nitide-glass.pdf>

I just found several through the glass antennas that I previously disected. Photos later...

eBay and Amazon have an assortment of Motorola antenna adapters.

I should mention there are adapter combinations that seems to be a
problem.  When the handheld radio has an SMA connector, using an SMA
to BNC or SMA to UHF adapter is a bad idea.  Like this:
<http://www.ebay.com/itm/220576696299>
These adapters are too weak to survive when attached to a thick heavy
coax cable.  Move the handheld, and presumably the coax will take the
bending.  However, if the coax is stiff, like RG-6/u, LMR-400, RG-8/u
etc, the adapter will take some of the bending force.  I've broken at
least two this way.  What I do now is make a short pigtail, with an
SMA at one end, and a BNC at the other.  The pigtail is made from
RG-58/u or LMR-240, which is sufficiently flexible to survive.

The one piece SMA to BNC adapters are better:
<http://www.ebay.com/itm/250930122068>
but don't quite fit every model radio with an SMA connector.  They all
need a rubber o-ring between the base and the case of the radio.
Without this o-ring, it's no better than the SMA to BNC adapter, and
the radio SMA connector is likely to break (or the plastic case).

You can also reduce some of the forces involved with one or two right
angle connectors, forming a swivel joint.

In a strong signal area, you probably won't see much difference.
Through the glass antennas work much better than a rubber ducky
antenna on a handheld. However, there's no comparison with a 5/8 wave
antenna with the vehicle roof as a ground plane. What's a "normal"
antenna and how did you do your testing?

>The type of glass can have a considerable effect on performance though,
>some of the 'tints' in windscreens do seem to introduce noticeable loss.

<http://www.pulseelectronics.com/products/antennas/larsen_antenna_products/technical_reference/faqs#On_Glass_Antennas>
You can also recognize passivated (coated) glass that won't work using
a "stud finder".   Metalized glass coatings will drive the stud finder
nuts. Glass without any metal inside will remain unchanged. There
are various suggestions on the web to use a capacitance meter. I

never could get that to work.

Argh.  That should be ...from a monopole WITHOUT a ground plane...

Good post.

All I can say is that the reason why a handheld works as good as it does
is because there is no feed line loss between the handheld and the
rubber duckie antenna.

When you add loss - you loose.

I have a 2 meters Radio Jap HTX 202 - ancient, that works with the
handheld antenna, but has a hard time doing it's job with a good Larsen
NMO 2/70 antenna on the roof.

Trying to put signal through glass is a lot like trying to supply a
cities drinking water through a common sippie straw.
YOu can get a little water through it, but not enough to make it worth
your while.

Kinda depends on the coax cable type and length. 25ft of RG58a/u or
RG174/u seems to be the standard. At 145MHz, that's 1.3dB and 2.6dB
loss respectively. With an alleged 2dBi gain antenna, the RG58a/u
coax loss is less than the antenna gain, resulting in net improvement.
With the RG174/u, there's a 0.6dB net loss.

The Radio Shack HTX202 is not my idea of a great radio. Favorite
problem is that it gets stuck in transmit with low battery voltages. I
probably have the same Larsen dual band antenna on my vehicle.
However, I'm using a Motorola Maxtrac on 2 meters, which works just
fine. The usual problem with HT's is that they can hear much better
than they can transmit. Vehicular power amps help, but the best
answer is a real mobile radio with decent power output.

>Trying to put signal through glass is a lot like trying to supply a

Roll down the windows?

The loss depends on the glass. I had no problems with my previous

vehicle, an Isuzu Trooper. However, my current 2002 Subaru Forester has coated glass everywhere, and is therefore problematic using a cell phone with the windows closed. I've done quite a bit of (paid and unpaid) tinkering with attenuation of wi-fi (2.4/5.6GHz) signals through assorted building materials, including glass. Unfortunately, I've done little tinkering with automobile glass. Attenuation through glass types used in buildings varies enormously. Clear window pane is almost totally transparent to RF. Titanium nitride coated double pane glass is about -20dB. Some others:
<http://wireless.navas.us/index.php?title=Wi-Fi#Attenuation>
The attenuation at VHF through coated single pane automotive glass will be much less than at 2.4GHz. I don't have a clue as to the number, by my guess(tm) is about -3dB for coated auto glass.

I can't do a simulation without dimentia, err... dimensions and
details on the transformer characteristics. Much as I like playing
with 4NEC2, measurements tend to be less forgiving.

The photo did not look like a 1/2 wave monopole, which does not
require a ground plane.
<http://www.panorama-antennas.com/index.php?route=product/
product&path=27_69_71&product_id=144>
It looks more like a 1/4 wave on 2 meters.

>Of course in a 50 ohm system the C value produced by the coupling unit

Yep. 1/2 wave monopole has a rather high input impedance and doesn't
require a ground plane.

>That tends not to be the case in the UK with most manufactures, although
>there is tinting it is not of the heat reflective variety.

If it's not for heat reflection, is there another reason to have
tinted glass on all the vehicle windows?

>The best type of coupling unit that I have found consists up a parallel
>tuned cct with the input coax earth connected to the bottom and the
>inner tapped some way up the coil, and the inside coupling plate
>connected to the top of the tuned cct. This is of course fairly narrow
>band but does work well on 2m.

Most of those require tuning. The glass thickness and composition also affects the tuning.

>This is of course a bit different to a cellphone system that requires a
>wide bandwidth.

Yep.

Jeff-

I didn't know it was for heat reflection, but that would be great if it works that way. I thought it was for privacy. You can see out, but others can not see in.

Visualize the automobile glass being made like green house glass.
Instant oven.

There's a simple test to see if the glass will pass IR. Find a
digital camera and a TV IR remote control. You can see the IR on the
LCD screen on most digital cameras. Put the camera inside the car,
and the remote on the outside. If you can see the IR LED's, the glass
is passing IR. If not, it's reflecting or absorbing IR.

However, that's near IR (0.700 �m - 1.4 �m) which is not heat. For
long wave IR (8 - 15 �m), use an optical IR thermometer gun and a heat
source. If it detects the heat source through the glass, it's passing
long wave IR. If not, it's being reflected.

Summary: Recruitment announcement for ham-radio-related FAQ articles
Keywords: FAQ, Intro, amateur, ham, radio, recruit, recruitment
Bytes: 3551
X-Received-Bytes: 3599

Posted-By: auto-faq 3.3.2 beta (PGPMoose V2.0, Perl 5.005)
Archive-name: radio/ham-radio/recruitment
Revision: 1.2 2009/11/25 14:41:01
Posting-Frequency: posted twice monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been recently revived by an active moderation team. We are currently seeking suitable information, FAQ, and bulletin articles from the entire rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our newsgroup.

We are seeking a replacement maintainer for the following information bulletin formerly posted to rec.radio.amateur.* (and currently archived at http://www.faqs.org/faqs/radio/personal-intro/):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

One significant omission, requiring immediate updates, for this article |
is that it does not mention newer amateur radio newsgroups created since |
it was written, including: |

rec.radio.amateur.antenna |
rec.radio.amateur.boatanchors |
rec.radio.amateur.dx |
rec.radio.amateur.equipment |
rec.radio.amateur.homebrew |

```
 rec.radio.amateur.moderated                                                 |
 rec.radio.amateur.space                                                     |
```

We are willing to provide any technical support necessary to get this article updated and automatically posted again at a regular interval. This would include establishing contact with the original maintainer for any necessary permissions. We would prefer to seek a new, dedicated maintainer at this time, rather than start auto-posting the original article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to rec-radio-info-request@panix.com.

A vertical antenna's gain is UNITY - 1

The only gain you can express is gain over Isotropic which would be
about 2.8 DBI - which doesn't mean anything.

To have gain over a dipole antenna, it would have to be larger and more
efficient then a dipole antenna - half wavelength in size..

>A vertical antenna's gain is UNITY - 1

Wrong. The type and length of a vertical antenna will produce different gains. Just look at any antenna manufacturers catalog. Simply mounting an antenna vertically does not magically give a unity gain.

>The only gain you can express is gain over Isotropic which would be
>about 2.8 DBI - which doesn't mean anything.

Wrong. The gain of a dipole antenna is generally considered to be 2.15dBi. It means that:

  dBd = dBi + 2.15dB

>To have gain over a dipole antenna, it would have to be larger and more
>efficient then a dipole antenna - half wavelength in size..

Wrong. It is possible to produce an antenna that is "larger" than a dipole, but has less gain. In general, bigger antennas do tend to have more gain, but there are some exceptions. A 1/2 wave dipole has a nice neat pattern that looks like a torus (donut) around the wire. Add additional 1/2 wave sections with the proper phase and the donut gets flattened, yielding more gain. However, it can also work the other way. Add phasing sections that tend to radiate along the wire axis, and you'll fill in some of donut hole. That will reduce the diameter of the donut, and thus reduce the gain.

What ever happened to creative test messages?
This is mine:
  This is only a test,
  I'm really trying my best.
  If this doesn't work,
  I'll feel like a jerk,
  and fix whatever I messed.

Required antenna related content:

Lesson learned this morning. Do not run RG-58a/u across a doorway at waist height as it can't be seen in the dark. I did a shoulder roll down a few stairs and landed on a pile of wet rubbish. Fortunately,

the badly assembled BNC connector attached to my service monitor fell
apart, preventing the service monitor from hitting the floor.

Incidentally, what I was doing was running a spectograph of FM
broadcast audio to see if the 19KHz pilot tone could be easily
extracted (to settle an arguement in sci.electronics.design).
<http://802.11junk.com/jeffl/crud/FM-19Khz.jpg>
May I suggest you download and play with the software. There's quite
a bit of useful stuff in there, much of which is ham radio specific.
For antennas, there's a direction finding display, which I have yet to
try.
<http://www.qsl.net/dl4yhf/spectra1.html>
Incidentally, contrary to the web page, it works fine under Vista
(32bit), which I was using last night.

Subject: Connecting built in antenna tuner to ladder line.
From: Tom W3TDH <hornetd@gmail.com>
Injection-Date: Sun, 25 Nov 2012 22:08:00 +0000
Content-Type: text/plain; charset=ISO-8859-1
```

Thanks to the generosity of a fellow radio club member I now have the use of a Yaesu FT-1000 (no Suffix). Since it has a built in antenna tuner, that I'm hoping to use, I need to ask what the best way is to couple the window line that feeds my folded dipole antenna into a short; say twenty feet; coaxial feeder from the radio. I used an Icom AH4 antenna coupler with my FT-857D on this antenna with very good results. I would guess that I need a balun but which type is a mystery to me.

So is a balun a good solution to this challenge or should I resort to the two pieces of coax in parallel that I have read of elsewhere? When you use the two parallel coax leads do you ground and/or bond the two shields at the transceiver end? Further since the FT-1000 does not have obvious balanced feed line terminals would I connect a balanced feed line to the ground terminal and the the center pin of the SO239 connector by using say a banana plug.

Since I really am asking questions I hope there is already a consensus
answer as I would not be able to sort out the various sides of any
debate. Thank you in advance to all who choose to tackle this
question.

Tom Horne W3TDH

Well, back in the mid-1960s, when I was building an EICO FM stereo receiver from a kit, there was circuitry dedicated to recovering the 19 KHz pilot tone, with a nice explanation in the assembly manual about how this new-fangled "FM stereo" stuff worked. Yes, indeed, it was trivially recoverable.

I built an Eico MX99 stereo decoder in the same time period.
<https://www.google.com/search?q=eico+stereo+decoder&tbm=isch>
I think I was 15 years old at the time. It worked, but not very well, because I managed to crack all the tuning slugs by using an Allen wrench instead of a plastic tuning tool. Some wax in the coil form was sufficient to hold the pieces of the tuning slugs in place. However, with tubes, the box tended to get hot, causing the wax to melt, which precipitated another retuning exercise. I eventually found a combination of ferrite pieces, metal scraps, and wax that would keep it tuned.

The discussion in sci.electronics.design on the topic was rather frustrating. The OP didn't answer my questions, kept changing the design target, was as vague as possible, and kept throwing in highly creative mathematical and software solutions to a non-problem. This was reinforced by a well known DSP expert, who claimed that the 19Khz signal could not be recovered. Welcome to usenet at its worst.

Yesterday, I did a careful inspection of my rooftop coax cable maze and found numerous pieces of outer jacket missing thanks to the local critters. From a cursory inspection, it appears that something had taste-tested my coax cables at fairly consistent 6" intervals. I have PVC conduit in the walls. I guess I now need it on the roof. Oddly, my radios still work fairly well with big pieces of the coax braid missing. Might as well junk the antennas and just use the chewed coax cable for an antenna.

I've been doing more work on the low frequency tuned loop antenna and have two problems. One is that I can't find any info on how effective the antenna will be in relation to the design parameters. That would be the diameter of the loop, the number of turns and the spacing of the turns. From the formulas I find for inductance, I would guess that the spacing of the turns will want to be as small as possible, but I'm not sure the factors that optimize self inductance are the same as what will optimize antenna effectiveness.

What equations determine the signal strength from a low frequency tuned loop antenna?

The other problem is finding an accurate formula for the inductance of this design. I've found a number of equations for coil inductance, but most are for coils with length longer than diameter. One I found doesn't say what it's limitations are and doesn't agree with the others. In fact, I can't find two formulas that approximate each other over the range of interest which is 1 to 20 turns or d/l from 4 on up.

I've consulted the Radiotron Designer's Guide, Nagaoka's and Lundin's papers on inductance of coils as well as a number of web pages. I'm getting tired of looking... Is there a reasonable formula for calculating the inductance of a short coil that works for a number of turns from 1 to 20?

Rick

> --
> 73, Cecil, w5dxp.com
>

No Cecil, I was not. I also would have given my s meter readings regardless of what I thought it should be. It is important to me to give my fellow hams as much good data on their antenna work as possible. I also agree that the hams that are asked about which antenna is sounds better should not know which antenna they are rating. I have a friend who has an inverted V dipole at 200 feet and a double bazooka as an inverted V at 75 feet. He is 100 miles away and the lower antenna is always the biggest signal. This does not make sense to me, but that is what is actually happening. The angle of both antennas are the same. We always need to measure actual performance and not paper performance.

I still think you should do this yourself. Just ABing the receiver is an important test. G5RVs have a reputation that I cannot personally confirm of being noisy. I do know for certain that some antennas produce more noise than others.

My loop does a wonderful job of nulling out the noise from my neighbour's homes and local industry.

Michael

On another list, populated by people with good guessing skills, poor memories and so on, the question of where did the RG numbers come from?

The most popular answer told with the most auhtority is that RG stands for "Radio Guide", as a device, the predecessor to wave guides.

I was under the impression, and may have read from a better source that it does indeed stand for Radio Guide, but that was a tile of a book.

Is that the case, are we all wrong?

If it is from the title of a book, does anyone have a link to, or can send me a (scanned?) copy of it?

TIA,

Geoff.

Geoff-

One problem I've found when researching old information on the internet, is that history appears to have started with the internet's invention. There is a lot of old printed data that may never be typed into machine-readable form unless someone needs it.

This is the first time I've heard this explanation of RG. It was my understanding that RG was a relatively arbitrary military designation. You will find other designations related to Co-ax connectors such as UG. I'd look for older military documents that listed various other designations, such as ARC-5, BC-459, et cetera, where each letter has a meaning related to the equipment's use.

I doubt that "guide" was used prior to microwaves. Co-ax has two conductors. A waveguide has a single "conductor": its inside wall. In other words, it appears to guide the energy rather than conduct it.

Fred

I've spent many years experimenting with G5RVs including field strength mea=
surements vs a dipole and a vertical. When someone has a problem with a G5R=
V on 75m, it is invariably because good engineering practice was not used i=
n that particular design and installation. An inverted-V at 15 feet with no=
 choke/balun and twinlead taped to a conductive pole and/or laying on the g=
round is certainly not going to work very well. With both antennas properly=
 designed and installed, it is difficult to tell the difference at resonanc=
e on 75m. However, the G5RV is fairly non-functional on 30m, 17m, 15m, and =
10m. 17m and 10m are necessities for me and that's why I don't use one. I b=
ought a G5RV in the late 80's expecting it to live up to its all-HF band ad=
vertising and I was disappointed. That's when I went to my no-tuner all-HF-=
band 130' dipole.

http://www.w5dxp.com/notuner.htm

Like any dipole where the two dipole elements are DC isolated from each oth=
er, the G5RV is susceptible to precipitation static. An RF choke across the=
 conductors will solve that problem.

You were VERY lucky that it worked the first time.
Be sure to check your transmit VSWR as it will change with two
antennas connected with a T connector.

Maybe those who chose a G5RV to buy something cheap and easy also then
erect it poorly. I have seen a G5RV erected in my town here. It looks
awful. It works just as well. I talked to another ham a few days ago on
40 meters. His G5RV was mounted at 10 feet. Some guys actually wind
their window line into a coil.

I also saw another antenna in town. It was supposedly a 75 meter zepp. It had 6 feet of window line and then a 60 of wire wound around a single tree. I am always amazed at the lack of planning and engineering that go into some antenna installations.

These guys will never have a good signal and probably never know why. Most will not ask for help because they already know that their antenna is great. I don't know why some hams will have their self-esteem tied up in their rigs and antennas. I mostly use an Icom 751A and I know it is not the best rig in the world. It is old and needs repair once in a while. My 75 meter loop at 35 feet of height is not the best antenna in the world, but it is the best I can do for height given my trees and property. However, I listened to someone who knew more about antennas than myself and he convinced me to change my window line feed to open wire. I got a huge benefit in performance. It does not make sense to me that a plastic dialectric is so much worse than air. Maybe it is the change from 450 ohms to 600. But boy did that antenna start working better.

Michael

The current consensus is that it means "Radio Guide" and that it was a big heavy printed book called "Army-Navy List of Preferred Cables" as part of MIL-HDBK-216. The problem is that nobody I can find has ever seen such a book or offered a scanned image of at least one page.
<http://www.avsforum.com/t/1433989/rg11-compression-connector-installation#post_22497621>
Note that the book was dated in the early 1960's. I believe coax cable was in use with the RG designation long before 1960. Methinks the whole thing is rubbish.

2nd best is "Radio Grade", which simply means that it's suitable for use on a radio. That begs the question why it would be necessary to even have such a designation, making that rather improbable.

My guess(tm) is that it's someone's initials or a combination of the last names of the draftsmen that were charged with documenting the cables. Coax cable was invented at AT&T by Lloyd Espenschied and Herman Affel in about 1928 or 1929, a patent issued in 1931, and commercialized in 1941. My guess(tm) is that the RG designation appeared somewhat after commercialization and sales to the military during WWII.

Original coax cable patent.

Hi OM Jeff,

Yes, I sure was!

You're correct - SWR is 3:1 with both the antennas connected.

I will get down to rigging a proper setup very soon.

Many thanks.

73

Nandu.

If the IMpedance is wrong, and the VSWR is 3:1

That means that the power has to travel up and down the coax 3 times before it is radiated.

If the coax is 50' long, 50 ohms and the frequency is 146 mhz and the loss rate is 3 DB in 50'.
Then you loose 9 DB of signal in each direction. transmit / receive...

So by knowing this - we now know that your antenna is not resonant - which is the reason why it is quieter - because it is not receiveing anything.

If we had to divide the frequency to get the antennas resonance to match 50 ohms - we now end up with a antenna system that is resonant somewhere around 70 MHz...

Sounds like you need to do a little more research before you post your findings on here.

The proper solution is to make phasing lines out of 75 ohm coax and get the two antenna's back in phase with each other.
The one antenna is cancelling the other out.

There's evidence that Oliver Heaviside patented a new arrangement of two conductors that would include co-axial in 1880, in a British patent numbered 1407. I haven't found a FOC source for downloading a copy of that patent but there's reference to it on the web (e.g. by Googling 'heaviside coaxial cable patent'). Google Books has 'Oliver Heaviside: The life, work and times of an electrical genius of the Victorian age' in which Page xvi refers. I didn't spot any reference to such prior art in the AT&T patent but, of course, they may have had no knowledge of something patented across the pond 51 years earlier ... particularly before the advent of under-sea co-axial cables!

However, where I used to work we had an extensive set of transcriptions of the work of Heaviside (Heaviside. O. Electromagnetic theory. Benn Brothers Ltd., London, 1922) and when I tried to research Heaviside's condition for a distortionless line (G/C = R/L) I was bogged down by an awful lot of waffle and found it impossible to determine what he actually meant by 'distortionless' - some say absence of dispersion, I thought absence of a limited frequency response. So, sacriligeous as it may seem, I wonder if the US patent is actually the first one about co-axial conductors that anyone other than the patentee actually understood!

<Channel.Jumper.ad71198@radiobanter.com> wrote:

>If the IMpedance is wrong, and the VSWR is 3:1

Yep. Assuming two perfect 50 ohm antennas (won't happen, but it's fun to imagine perfection), in parallel give a 25 ohm load. That's a:
  50ohm / 25ohm = 2:1 mismatch.

>That means that the power has to travel up and down the coax 3 times
>before it is radiated.

Nope. That's not the way it works. VSWR is simply the ratio of the load impedance to the system impedance. On a non-leaky system, reflections create standing waves, with voltage peaks and nulls that can be measured and used to calculate the VSWR (or reflection coefficient).

There's nothing in the formulas to suggest that VSWR has anything to do with the number of "bounces". Were your statement true, then I would assume that after 3 bounces, the signal would magically disappear. That doesn't happen because the signal is not a lump of RF, or some quantity that has a finite beginning or end. It's a CW (continuous wave) signal, that is being produced continuously (as long as the power is applied), producing standing waves. What RF is being reflected by the load, is being bounced back to the source continuously and therefore never disappears (until someone pulls the plug).

In addition, there's really only one bounce. If you assume that the xmitter source impedance is 50 ohms and the line impedance is 50 ohms, then when the reflected signal bounces back to the transmitter, there's no mismatch. Therefore, the xmitter absorbs all the reflected power, and does not send any of it back to the load again. This is why transmitting into a short or open causes so much trouble with transmitter output stages. The reflected power equals the source power, and all of it has to be dissipated in the output stage. Were the reflected signal be able to bounce back for a 3rd pass (as you claim), it would really be wonderful because no excess power would be dissipated in the xmitter output stage.

>If the coax is 50' long, 50 ohms and the frequency is 146 mhz and the
>loss rate is 3 DB in 50'.

Loss is not a rate. Loss does not change with time. You don't read about dB/minute. There is dB/ft, but that's not a "rate".

>Then you loose 9 DB of signal in each direction. transmit / receive...

Nope. A VSWR of 3:1 is a return loss of 6dB.
  Return-Loss = 10 log (Pin / Power-reflected)
  (Pin / Power-reflected) = 4:1
So, with a VSWR of 3:1, for every watt that gets transmitted, 0.75 watts gets radiated by the antenna, and 0.25 watts gets reflected back to the transmitter, where it is absorbed and dissipated as excess heat by the power amplifier (assuming 100% efficient antenna, loss less coax, and 50 ohm xmitter output PA).

>So by knowing this - we now know that your antenna is not resonant -
>which is the reason why it is quieter - because it is not receiveing
>anything.

It's not receiving the noise because the combination of the two antennas has produced a null in the antenna pattern conveniently pointed in the direction of the noise source. Presumably, signals from other directions work somewhat normally.

>If we had to divide the frequency to get the antennas resonance to match
>50 ohms - we now end up with a antenna system that is resonant somewhere
>around 70 MHz...

Nope. If that were true, then 4 bay stacked dipole collinear antennas would not work. Each dipole is tuned to the operating frequencies. Put 4 of them on a pole space 1/2 wave apart, add a tangle of phasing coax cables, and you have an antenna that is resonant exactly at the same frequency as the individual dipoles.

>The proper solution is to make phasing lines out of 75 ohm coax and get
>the two antenna's back in phase with each other.
>The one antenna is cancelling the other out.

That's what he's trying to accomplish. He's trying to put a null in the direction of a local noise source.

Posting-Frequency: posted twice monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35f23326

the rec.radio.amateur.moderated Moderation Team had decided to consider |
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. After a successful trial |
period (90 days, through early July 2009), we decided to adopt this |
change permanently. |

Approved rec.radio.amateur.* newsgroups are those that are currently listed in the latest version of the "List of Big Eight Newsgroups" which is crossposted monthly to news.announce.newgroups, news.groups, and news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those that have been created consistent with the suggestions in "So You Want to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either "radio.amateur" or "ham-radio" in their names, including uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved newsgroups up-to-date. In case we have overlooked any, and a submission is rejected in error as a result, the rejected submitter can E-mail us at our administrative contact address (in the signature at the bottom of this article, and the default Reply-To for the rejection message) requesting that it be added, and that the article be approved. We may still choose to reject articles crossposted to any alt.* newsgroup with an inappropriate name, including obscene language, embedded name-calling, or encouragement of unlawful conduct.

Please direct any comments, questions, or criticisms to rec-radio-amateur-moderated-request@panix.com.

The both halves of your antenna work in each cycle as the radiator and next
as the counterpoise.
For the counterpoise the bare wire is better than the insulated.

Maybe he needs to get with this man and come up with a whole new theory on swr.
http://www.youtube.com/watch?v=zOOihiLLS4I&feature=related

I see that much progress has been made on the SWR theory from the time I passed the First Class Radiotelephone back in 1972. Kraus was wrong :-)

Ah, but if it were true, it would certainly be useful. Since a short circuit can produce infinite VSWR, the signal would bounce back an forth an infinite number of times. Just transmit some RF into a shorted piece of coax cable, unplug the trasmitter, replace the transmitter with another short circuit, and you have an "RF power Storage Bottle(tm)", with the signal bouncing back and forth forever. When you need some RF, just uncork one end of the coax cable, and out comes the stored RF.

Well, to be (uncharacteristically) honest, one doesn't need a magic reflecting VSWR theory to build my perpetual RF motion machine. It would be easy enough to just put a T connector half way between two pieces of shorted coax cable. Apply some RF to the T connector, disconnect the transmitter, and cover the T connector. The RF should bounce back and forth between the coax end points forever. All one needs is lossless coax, superconducting lossless conductors, and lossless vacuum dielectric. I don't think a cork would be necessary.

Hello Jeff.

I wonder how long it will be before lossless coax, superconducting lossless conductors and lossless vacuum dielectric become a reality?
What other, currently theoretical, components could we make use of? I like portable operating so I'd go for an AA cell that can hold at least 100 Watt hours of power. I'd settle for a soldering iron that can melt solder but is well enough educated not to burn me when I grab the wrong end.

73 Ian.

Hi,
I am blessed to have the DX-CC land in my lap, but used and soon will need rewiring. Any advice on those coils? Can they just be re-coiled with the same wire all along? I have a large coil of solid copper wire that is 12g with the plastic jacket with a uv thin sholack. What are the recemmendations for the coil turns and lengths of that coil wire?

or am I better off replacing those coils with exactly the same size enammeled copper wire with two solder joints? Same as the manufacture does. Would they just do it this way to speed up the process? Make it easier for mass production?

If I were to wire that top leg all same wire including the coils, is that preferred? Any ideas as to the specs for doing it that way if you guys think that is electrically more logical? Or not?

Thanks

73s

Room temperature super-conductors are a possible solution.
<http://en.wikipedia.org/wiki/Room-temperature_superconductor>

>What other, currently theoretical, components could we make use of?

The list is huge. Just about any device that is plagued by IR losses
would benefit. You can already by superconductor wire:

<http://www.suptech.com/hts_wire_overview.php>
The RF application is superconducting wire and ceramics for low loss cell site filters and front ends:
<http://www.suptech.com/superlink_850.php>

Superconducting power transmission lines are being tested:
<http://en.wikipedia.org/wiki/Electric_power_transmission#Superconducting_cables>
In theory, the energy necessary to keep the transmission lines cold is less than the energy loss that would be produced if they were made from the traditional aluminum conductors.

>I like
>portable operating so I'd go for an AA cell that can hold at least 100 Watt
>hours of power.

Different animal. 100 watts for how long? We're talking energy here, as in Joules or watt-seconds, not just power in watts. I can easily give you 100 watts to heat your soldering iron, but only for a few seconds. If you want to use it for more than a few seconds, you'll need more energy, or more specifically, more energy density.
<http://en.wikipedia.org/wiki/Energy_density>
(It might be helpful to know that 1 kw-hr is 3.6MJ). Just pick your energy source and calculate how long it will run a 100 load. For example, the AA alkaline battery holds 15,000 joules and will run a 100 watt load for:
   15,000 watt-seconds / 100 watts = 150 seconds
which will never happen because the internal resistance of the battery will first will convert much of that energy into heat. You're probably better off soldering with something that is converted directly to heat such as a butane soldering iron, rather than being converted to electricity as an intermediate step.

Incidentally, the only difference between a battery and a bomb is the energy density. As you climb up the table towards increasingly larger energy densities, you rapidly approach a weapon of mass destruction.

>I'd settle for a soldering iron that can melt solder but is
>well enough educated not to burn me when I grab the wrong end.

No problem. See:
<http://en.wikipedia.org/wiki/ColdHeat>
This soldering iron tip has so little thermal mass that it heats up and cools down very quickly. Touch the tip after soldering, and you won't get burned.

Hi,

Does anyone have a working CTCSS board for an FT290R MkII for sale?

If you have one, or if you know where I can get one, please email me at g8put@g8put.com

Regards
Chris, G8PUT

I've finally found the last of my QSLs from my period as a SWL of the
ham bands (1977 and 1983-85) and have been loading them into my
computer.

I have a question of prefixes- one country in particular- East Germany.

A typical EG call would be Y23AZ. Now, is the prefix Y2 or Y23?

If it still works, I see no real need to rewire. The green
coating is not going to hurt anything, unless it's so severe
the wire is rotting away. Or if the coating causes a short
between windings for some reason. If not, I would just use
it as is.
But if you really feel compelled to rewire it, I would use
the same exact gauge solid wire that was originally used.
That way you can use the same forms with no design changes.

I am looking to build a LF antenna for a home built WWVB receiver and have found a number of antenna designs. The ones that might be best look like shielded loop antennas. Here is a pretty good page showing construction of one.

http://w5jgv.com/rxloop/index.htm

I will be looking to get as large a signal out of the antenna as possible without using a preamp. From what I can tell, I will want to use as many turns as possible, limited by the upper frequency of the antenna. I assume this is because as the cable gets longer the self resonant frequency drops.

Am I headed down the right path? The only other antenna I have found for LF work is a ferrite core coil antenna, but my impression is that they don't pick up as large a signal. That is somewhat mitigated by the fact that nearly every crystal radio that isn't connected to a long wire is connected to a ferrite core. These are powered by the received signal itself, so it must pick up some decent signal. Then again, I think they mostly pick up local stations without a very optimal antenna, no?

I'm interested in any sources of info that might help me in my planning.

Rick

It is possible to have zero losses in a DC steady-state superconducting system that is free of collisions, i.e. no particle acceleration. However, RF (AC) guarantees particle acceleration and collisions which are a type of friction.

Oh, so that's what you were asking in sci.electronics.design.

>The ones that might be best
>look like shielded loop antennas. Here is a pretty good page showing
>construction of one.
>http://w5jgv.com/rxloop/index.htm

Yep. Loops are good. However, there are smaller, cheaper, and possibly more appropriate antennas available if you have a fairly good signal. That's the real problem. At 60KHz, the atmospheric noise is sufficiently high to bury even strong signals. Worse, the propagation varies with the time of day.
<http://tf.nist.gov/stations/wwvbcoverage.htm>
<http://tf.nist.gov/tf-cgi/wwvbmonitor_e.cgi>
<http://www.febo.com/time-freq/wwvb/sig-strength/index.html>
Adding more antenna gain does nothing as it increases the received noise and signal equally. The ratio (i.e. SNR) remains the same.

More on the subject of WWVB antennas at:

That's possible, but preamps solve lots of problems. The big one is

```
the impedance match between the loop and the receiver input.

Sorta.  What really happens is that you can build an antenna for size,
bandwidth, or gain, pick any two.  Building a larger antenna will
yield more gain or more bandwidth (but not both).  The little tiny
ferrite loopsticks are the same, lacking in either gain or bandwidth.
>
>Am I headed down the right path?

Dunno.  I'm not sure what you're trying to accomplish and what
limitations on cost, size, weight, power, etc are involved.

Hey gang, i was working on my full wave horizontal 80 mtr loop and decided to add either an "ugly balun," or possibly a dx engineering 1:1 balun. The antenna is abt 275 ft long and is currently just fed directly with coax, and I use it for 10-80 operation with a tuner.

Obviously, i like the cost of building an ugly balun, but will it work as good as the 1:1 dx engineering balun? Thanks in advance.

Here's some information: http://www.karinya.net/g3txq/chokes/

As you can see, there are none of the air-core baluns that work very well 8=
0m-10m because they are narrow-banded. Note that 25 turns is not enough tur=
ns for 80m and too many turns for 10m. Compare the bandwidth of the ferrite=
 toroid baluns to the bandwidth of the air-core baluns. (We might define th=
at bandwidth as any color except red, i.e. any frequency where the choking =
impedance is greater than 1K ohms.)

  Hey Jeff,
  I did some searching for info for him but didn't find a lot on just a
loop resonant at 60 Khz. I was looking for turns and capacitance but
found no designs.
  So I think he needs to pick a size that he is comfortable with and
calculate turns somewhere between 100uh and 200 uh and find some
polystyrene 10,000 pf caps put 4,5, or 6 in parallel and then find a
large air variable to fine tune it with. (135uh and 5000pf is resonant
at 60khz) Then he needs a matching pickup coil, I've seen a small coil
about 1/5 dia. of the larger coil used. There are other methods.
  Should he use coax? Wrap it with foil when complete? (with gap)
   You're thoughts? (maybe more uh's?

kb8viv, you need to give use some idea on the physical size you can
tolerate. also, are you sure you don't want a preamp?
                                 Mikek

You would likely get better results if you did a specific Google search,
i.e. WWVB antenna.

There are lots of articles out there specifically for WWVB antennas
and receivers.

Here's some:

http://www.febo.com/time-freq/wwvb/antenna/index.html

http://www.ka7oei.com/wwvb_antenna.html

http://www.moorepage.net/Loop.html

http://www.creative-science.org.uk/MSF3.html

Ok, let's do the math (for the 2nd time as my PC crashed in the middle of the first attempt).

The loop antenna is basically an impedance transformer. To feed with 50 ohm coax and no preamp in the antenna, the require turns ratio is:
(main-loop-turns / 1-turn-coupling)^2 = Xl-main-loop / 50 ohms
Using your 0.01uF tuning capacitor, which has a reactance of:
Xc = 1 / (2 * Pi * Freq * 0.01uF) = 265 ohms
At resonance, the inductive and capacitive reactances are equal.
Plugging in, I get a turns ratio of:
sqrt (265 / 50) = 2.3
which isn't very practical for a loop antenna. To get a higher turns ratio, a smaller cap will be needed. For example, with 1000pF, the reactances are 2600 ohms for a turns ratio of 7.2, which is somewhat better. The main loop and the coupling loop would need to be rather close together. No problem with a ferrite core, but not very practical with an air core shielded loop. You could use your 1/5th size coupling loop (as is used in a magnetic loop HF antenna), but at 60KHz, efficient coupling will not happen. The loops need to be physically close (or wrapped around a ferrite rod). However, a tapped loop would work if you insist on not using a preamp.

The more common way is to use a preamp at the antenna. It's purpose is to amplify the received signal, but also to deal with the loop to coax impedance conversion. See the schematic at:
<http://www.ka7oei.com/wwvb_ant_1_1.gif>
Note that the amp if connected directly across the main loop. The 0.4uF tuning cap yields a reactance of 6.6 ohms, so the 1K amplifier input resistor will have no effect on Q. I would have used a smaller capacitance, but since the author elected to use a bipolar xsistor instead of a FET, the lower reactance will result in a smaller voltage swing and will help prevent clipping.

Then, there's bandwidth or Q. The main loop will probably require
about 15ft of #26awg wire according to some of the construction
articles. At 0.041 ohms/ft, 15ft = 0.6 ohms.
   Unloaded Q = Xl / R = 265 / 0.6 = 440
So, the -3dB bandwidth of the loop will be:
   60Khz / 440 = 135 Hz
Since the bandwidth of WWVB is about 700Hz, that should work. It will
never really have a Q of 440 due to loading and losses, but that
should give a clue on how critical the tuning might become with a
huge, single turn loop. Incidentally, I was aiming for a Q of about 5
on the LORAN antennas which was required because the 100KHz LORAN
signal is 20KHz wide. Loops were possible, but amplified whip
antennas were much easier to deal with.

Thanks for the reply.   At this point I may just forego the balun all
together and continue to just feed theloop with coax. Thanks again es
73's.

This may be a wrong assumption. This antenna will be very close to the
receiver and this is a home brew receiver, not a commercial one. I can
make the input impedance anything I want really. I am looking at
directly driving a high impedance input on the ADC. Is there some
reason to work with a lower impedance for a very short run?

BTW, I have seen loop coupled antenna described but one of the pages I
found talked about the complexity of correctly coupling the antenna to
cables, not just impedance, but the balanced/unbalanced issue. This web
page seems to talk about it pretty well.

http://www.w8ji.com/magnetic_receiving_loops.htm

The page I refer to in my original post uses a toroid transformer to
couple the output to the antenna rather than a loop. I like the idea,
but I have no idea how to calculate the number of turns on the toroid.
His app was for 50 ohm cable and a higher frequency than mine.

http://w5jgv.com/rxloop/index.htm

I think this guy did a lot of research in designing his antenna and was
very skilled in building it.

I'm a bit unclear on this. Is the 2.3 the number of turns in the primary loop to one turn on the pickup loop? What is unpractical about that? Or is this the other way around with 2.3 turns in the pick up to one turn on the antenna primary?

In case you haven't figured it out, this is my weak suit. I didn't have a lot of the core courses in various EE disciplines while focusing on digital. I've picked up a lot over the years in the analog domain and signal processing, but am still rather weak in E&M. On the other hand, I got an 'A' in P-chem! In terms of flunking undergrads, that is the chemistry equivalent of E&M theory in EE.

The spacing seems to be a critical factor for optimizing transfer of energy. One web page talked about spacing the pick up loop, not too far and not too close.

What exactly is a tapped loop? I'm not picturing this.

I'm thinking of maximizing the voltage out of the antenna into a high impedance load. Is that not a good thing to do? With the direct RF sampling by the ADC I need as high an input as I can get.

> <http://www.ka7oei.com/wwvb_ant_1_1.gif>

Yes, I've seen this page. I noticed that he used steel conduit for the shield and another page says to avoid magnetic materials for the shield, although I expect the magnetic shielding of thin wall conduit is minimal.

> Note that the amp if connected directly across the main loop. The 0.4uF tuning cap yields a reactance of 6.6 ohms, so the 1K amplifier input resistor will have no effect on Q. I would have used a smaller capacitance, but since the author elected to use a bipolar xsistor instead of a FET, the lower reactance will result in a smaller voltage swing and will help prevent clipping.

Really? Clipping is a concern? These antennas are typically very highly peaked at the frequency of interest and I don't expect much interference from strong sources like AM radio stations. Would the clipping just be from noise? My understanding is that here, on the east coast, it is hard to receive WWVB but then that is likely with ferrite antennas. Will a large loop, say 3 foot diameter, pick up a significantly larger signal?

> Then, there's bandwidth or Q. The main loop will probably require about 15ft of #26awg wire according to some of the construction articles. At 0.041 ohms/ft, 15ft = 0.6 ohms.

Is the bandwidth that wide? The signal is AM and BPSK modulated at 1 Hz rate with minimum modulation periods of 0.2 and 0.1 seconds respectively. I'm surprised the BW is that wide. I understand that the sharp edge of the modulation requires some bandwidth beyond the bit rate. But a document I found on a government page says the antennas only have bandwidths around 260-310 Hz. But they also say the "system bandwidth" is 5 Hz based on the AM pulse width minimum of 200 ms. I'm not sure this is a good way to figure it.

> It will
> never really have a Q of 440 due to loading and losses, but that should give a clue on how critical the tuning might become with a huge, single turn loop. Incidentally, I was aiming for a Q of about 5 on the LORAN antennas which was required because the 100KHz LORAN signal is 20KHz wide. Loops were possible, but amplified whip antennas were much easier to deal with.

I would be doing simulations on the digital design, but I found my FPGA software license is out of date. Good thing I didn't get pulled over! :^) But I'll have to wait until tomorrow to get a new license so I can work on that.

So many pages, so little time. I realize that the issues of coupling are *solved* by using the loop coupling just like the ferrite core coupling. Opps.

A fair number of LF loop antenna I have found don't bother with this, but many do.

What will be the impact of not having an actual ground connection anywhere? Will it be important for the shield to be grounded to a "proper" ground to be effective? There will be no power line connection for this device.

Rick

Thanks for the suggestions.  I have looked at dozens of pages so far.
Many of them are very good, but they only talk about what they did and
don't actually teach so much.

I have a 75 meter loop. I feed it with 600 ohm open wire ladder line. I have experimented with coax and window line.

The 600 ohm ladder line is extremely low loss. This makes up for the nasty mismatch on 75 meters. This scheme got me an antenna that works on 10, 15, and 20 with no tuner. The VSWR is less than 1.6:1 on the worst spot on these bands.

I use this antenna mostly on 75 meters and it works very very well. For some reason I cannot say, the side null of noise from town increased and I got less noise on all bands switching from 450 ohm window line to open wire ladder line. I cannot explain why this happened. It is very nice to see a S0 noise reading on 20, 15, and 10. My 75 meter noise is still between S2 and S3. However, that is quite a step up from what I had originally.

I think the good match on the high bands is because the loop feed point gets higher in impedance at the higher frequencies.

I checked my worst case losses with a calculator on the web. It is found here http://www.kc9aop.net/HAM/antenna_facts.htm#trans_line_loss_calc

Mine calculated out to be about 1/2 db at 75 meters.

Michael

Hi Michael,

Tnx for the reply and info. At this point it works well, so I think I'll just run the coax with a few loops at the feedpoint and call it fit for service. Tnx agn es 73's.

I don't have any of the math for you. However, I know what works and what does not. You probably do not listen to your own G5RV. Its poor performance is pretty clear to anyone who listens to you. However, if you have an emotional bond with your G5RV, I would not want to be the cause of any alienation in your relationship. Keep using it. The low effective radiation makes for more band space for the rest of us. The signal just disappears into the noise level.

Better yet just put up a random wire and a water pipe for ground. You can get a perfect match with a tuner. It will work better than the long wire the guy wanted to bury in the ground :-) In fact I recommend you try burying your G5RV and make a stealth G5RV. It will still load with a good tuner.

However, if you were actually interested in improving your transmitted and received signal, you might tune around 75 and listen to those stations putting out a big signal. Especially in the daytime when band conditions are bad. Ask someone with that big signal what antenna they are using. If they are using a G5RV then you are right and I am wrong.

Michael

I doubt if many will choose to use a G5RV when they can put up a 'better' antenna, and it's unlikely that the stations putting out really big signals are using one. However, subject to an appreciation of its characteristics and limitations, it can usually be made to perform reasonably well.

Regarding the use of shorter-than-halfwave dipoles, the following writings of W8JI (and the included links) are worth a read.
http://www.w8ji.com/short_dipoles_and_problems.htm

I've had a quick look, and it seems that the main cause of poor efficiency/performance is that as the dipole is progressively shortened, the increasingly high SWR causes high losses on the feeder. Cunningly minimise the SWR, and you can still have a reasonably efficient radiator.

It may also be useful to look at one of G4FGQ's programs - 'Dipole3'. If you enter zero feeder lengths, this gives a quick assessment of the efficiency of the dipole alone.
http://www.zerobeat.net/G4FGQ/page3.html

> I don't have any of the (G5RV) math for you.

Allow me to provide it based on EZNEC simulations and VK1OD's transmission line loss calculator. The G5RV will be compared to a 127 foot coax-fed dipole, both at a height of 40 feet and both antenna systems resonant at 3.72 MHz.

The 127 foot dipole has a maximum gain of 6.42 dBi at TOA of 90 degrees.
The G5RV dipole has a maximum gain of 6.06 dBi at TOA of 90 degrees.

The 127 foot dipole has a gain of 4.65 dBi at an elevation angle of 45 degrees.
The G5RV has a gain of 4.37 dBi at an elevation angle of 45 degrees.
The dipole beats the G5RV by 0.28dB

The 127 foot dipole has a resonant feedpoint impedance of 59 ohms at 3.72 MHz.
The G5RV has a feedpoint impedance of 33-j355 ohms at 3.72 MHz.

For 30' of RG-213, the 127' dipole has 0.093dB loss.

For 30' of 300 ohm twinlead, the G5RV has 0.89dB loss.
The 127' dipole beats the G5RV by 0.8dB

For another 50' of RG-213, the 127' dipole has 0.175dB loss.
For 50' of RG-213, the G5RV has 0.241dB loss.
The 127' dipole beats the G5RV by 0.066dB

The 127' dipole beats the G5RV by 1.15dB which is 20% of one S-unit. Human ears can barely detect a 1dB change.

So please explain to us how one signal that is 1.15dB lower than a second signal can "disappear into the noise level" and why your ears are so much better than the ears of normal homo sapiens.:)

Some hams think that -1.15dB on 75m (20% of one S-unit) is a rational compromise for an antenna that also works well as is on 40m, 20m, and 12m.

Random wire and water pipe was what got me hooked. Now I have lots of land behind my home for a real nice long wire but I cant get the wire across to my property :(

Dear "gipy" (no call sign provided):

From what you have written, you must get a transmission line across a "common area" (of something like 20 feet) to a long piece of property that you control, and the only acceptable scheme is to bury the TL. For a transmitted signal (I am assuming that you might be a radio amateur) a buried, single wire TL of only 20 feet would result in little signal reaching an antenna - so such a TL is counter-indicated. One could support a twin-wire (two parallel wires) TL within a buried, larger-diameter "plastic" conduit for 20 feet and not loose much, however you would have to craft a scheme for supporting the twin-wire TL in the approximate center of the conduit and the installation is likely to be provocative to other users of the common area. So, coax it is. To have the coax have little loss you must use BIG coax or not let the SWR get too large.   By stages, arrive at the conclusion you stated that the way to go is to use coax with a good quality, autotuner at the far end (and a good ground). One can use a spade (or one of many other tools including a larger knife) to slit the soil and insert coax.

You will find it instructive, once you know the geometry of your long-wire to use a computer program like EZNEC to get an idea where lobes are expected. After you install, let the group know what you did. 73, Mac
N8TT

"gipy" wrote
I am in a situation where I HAVE to bury the feedline, there is no other way around it. I have trees about 20 feet away from my home in the back, great for swinging a long wire, dipole, whatever works but being that the actual space between the trees and my home is a common area, I have to bury the coax.
Placing a remote tuner on the other side would be a bit of a hassle but I see its starting to look like the only way to go?
I got plenty of time, I just want to do this once and the right way.
Again, any thoughts appreciated and thanks to all who have posted, it is turning out to be a very interesting thread.

At my location I receive static-type QRM across the 2m band with either of my antennas (a 1/4&#955; Ground Plane 15m high & a Slim Jim 10m high). As it's not present at night and on weekends I presume the source is commercial.Very strong signals override the QRM but with weaker signals its a nuisance.When I connect both the antennas to the rig through a 'T' connector, the 'S' Meter reading drops but the QRM disappears and the audio level goes up considerably.SWR is 3:1 with both the antennas connected.73Nandu.

Look into vertical antennas with a cardiod pattern. I use these for direction finding, but they also are good for putting a notch in one direction (such as a co-channel interfering repeater).

Basically, it's two IDENTICAL antennas, spaced 1/4 wave apart. Put a Tee connector on one antenna. Run 1/2 wave electrical length coax between antennas. The feed coax goes to the other port on the Tee connector.

4NEC2 has such an antenna in its sample antenna collection. Look for:
   C:\4nec2\models\HFvertical\CARDIOID.NEC
   C:\4nec2\models\zz_EZnec\v3.0\Cardioid.nec
Note that the frequency is 299MHz which yields a wavelength of exactly
1 meter. You can use that to scale the antenna to any convenient
frequency. After a quick run through the optimizer, I got a F/B ratio
of about 50dB, which should be deep enough to null out your noise
source. However, if the signal is bouncing off of nearby buildings,
and arriving from other directions, this is not going to work.

Subject: AM but no FM on Timex T311 clock radio - Single Wire antenna
From: goldenhound104@gmail.com
Injection-Date: Sat, 20 Oct 2012 07:07:17 +0000
Content-Type: text/plain; charset=ISO-8859-1

Not sure if this is the right group, but here goes.

I have a Timex T311 clock radio. Seems like it used to get FM, but now all I get
is a single statiky station across all FM frequencies. Uses a single wire antenna
about 20" inches long.

Pulled it apart and the wire is connected to a board. The placement of the wire
is hard to see, with a blob of hot glue on the connection.

Is the antenna broken, or something else? Curiosity more than anything.

Thanks in advance for any help!

I don't believe in luck, but have been known to rely on it. In this case, I've built several cardiod pattern antennas for direction finding and for unwanted repeater notching. They work.

However, I screwed up in my comments. The antenna spacing can be almost anything as long as the DIFFERENCE between the phasing line delay and the antenna spacing is a multiple of 1/2 wave, so that they cancel. In my original comment, it should have been 1/4 wave spacing, and 3/4 wave electrical coax cable length.

One problem with such designs is that they are very frequency dependent. My guess(tm) is that the usable bandwidth of the notch at 2 meters is about 200KHz. At any other frequency, the notch depth is somewhat lacking. It also doesn't solve the noise problem if a different style antenna (i.e. anything direction) is used.

>There are both designs and commercially available

Yes, that's what he wanted. I was proposing a simple alternative.

Antenna noise cancellers. HF only:

According to the FAQ, that's the FM antenna:
<http://www.timexaudio.com/faqs.asp?Productid=10108>

>Pulled it apart and the wire is connected to a board. The
>placement of the wire is hard to see, with a blob of hot glue

>

> Is the antenna broken, or something else? Curiosity more than anything.

Break off the yellow goo. Find a 20" piece of wire, and connect it to where the the antenna attaches. If it works the same, it's not a broken wire antenna. I can't tell from here what is broken. My guess(tm) is that it's something else. Since you can hear one station, the FM receiver is functioning and just lacking in sensitivity. That would mean a problem with the 20" antenna or the receiver front end (RF amplifier section). Since it's probably an all digital receiver, it's probably something blown in the AM/FM receiver chip.

Just spin the antenna around until the noise goes away. That's the way it works in a direction finder. The only luck that would be required is to hope that the noise source and the station he's talking to are NOT at the same bearing. In that case the antenna would notch out both the desired signal and the noise.

However, we're both assuming that the noise is being radiated by a point source. If it's being conducted through the power lines, there's no single direction that could be nulled. The noise will appear to be coming from all directions. The cardioid notch antenna will be totally ineffective. The antenna noise canceller might still work (not sure).

AC power in India is not the best. I'm not surprised that there may be some "industrial" noise:

Hi OM Jeff,

Yes, I should check that.

Trials with a 2-element vertical array and a Moxon (both homebrew) were unsuccessful.

Many thanks.

73

Nandu.

Hi OM Jeff,

I think it's not powerline noise. A 2-element array/a Moxon have confirmed that it's from a point source.

73

Nandu

P.S. I am indeed horrified by those photographs!

If that's true, and it's coming from one specific direction, then the
cardioid antenna pattern should have reduced the noise level. My
guess(tm) is that you did something wrong with the construction of the
antenna. Did you test for a notch with a local repeater at a know
location? Just spin the antenna around. If you get a null in the
direction of the repeater, it's working. If not, something is wrong
with the antenna. If you do get a null, play with the antenna spacing
to produce the deepest notch. Note that you will need to retune if
you change frequency.

The one at:
<http://tinyurl.com/9dn3xfm>
is truly amazing. Everything is a ground level. Barbed wire at the
base to keep the kids from riding their bicycles under the
contraption. The dolly wheels are still attached to the bottom of the
transformers, which appear to be welded in place. There's a small
platform nearby which appears to be a cell phone charging station. It
looks like this thing in parked in front of someone's front door. Is
utility power really this bad in India, or are these photos just
atypical horror stories for the benefit of the media?

Hi Jeff,

Thanks for the brain-slice even though its in the wrong group. I'll pull it apart again, and try what you suggested. THANKS!

Rob

I don't know for sure. His comments were:
   "Trials with a 2-element vertical array and a Moxon (both homebrew)
   were unsuccessful."
I assumed that the "2-element vertical array" was a genuine cardioid
notch type array built in the manner I described. Perhaps not.

Want me to post the NEC2 deck and resulting patterns?

Summary: Recruitment announcement for ham-radio-related FAQ articles
Keywords: FAQ, Intro, amateur, ham, radio, recruit, recruitment
```

Bytes: 3552

Posted-By: auto-faq 3.3.2 beta (PGPMoose V2.0, Perl 5.005)
Archive-name: radio/ham-radio/recruitment
Revision: 1.2 2009/11/25 14:41:01
Posting-Frequency: posted twice monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been recently revived by an active moderation team. We are currently seeking suitable information, FAQ, and bulletin articles from the entire rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our newsgroup.

We are seeking a replacement maintainer for the following information bulletin formerly posted to rec.radio.amateur.* (and currently archived at http://www.faqs.org/faqs/radio/personal-intro/):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

One significant omission, requiring immediate updates, for this article |
is that it does not mention newer amateur radio newsgroups created since |
it was written, including: |

rec.radio.amateur.antenna |
rec.radio.amateur.boatanchors |
rec.radio.amateur.dx |
rec.radio.amateur.equipment |
rec.radio.amateur.homebrew |
rec.radio.amateur.moderated |
rec.radio.amateur.space |

We are willing to provide any technical support necessary to get this article updated and automatically posted again at a regular interval. This would include establishing contact with the original maintainer for any necessary permissions. We would prefer to seek a new, dedicated maintainer at this time, rather than start auto-posting the original article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to
rec-radio-info-request@panix.com.

Hi OM Jeff,

You are absolutely correct. Mine is a 'chance-phase-cancellation' setup.
It's proven, since the noise returns when either feeder length is
incremented randomly.

What be the result of stacking two (theoretical) isotropic antenna.

If the output from two (theoretical) isotropic antennas was to be combined in phase and measured would there be a gain? And if so where is the gain coming from, I'm thinking of the distorted balloon model to explain antenna gain.

Regards

Peter

Welcome To Cheap NFL Jersyes Store!We the promise to you:GREAT QUALITY
+ FAST SHIPPING + ENTHUSIASTIC SERVICE = 100% SATISFACTION.
1.Men and women jersey free shipping order over 10 Pieces(can be
mixed).
2.100% recycled polyester.
3.designed for movement.
4.Player's name and number.
5.Strategic ventilation for breathability.
6.Player's number sewn on the shoulders,upper back and on the front of
the jerseys.
7.NFL Equipment patch patch sewn at the point in the front.
8.Good NFL Jerseys Shop.
We have the size S to XXXXL,But we have to distinguish a point:our NFL
women jerseys only have the size from S to XXL,and the man is M to
XXXXL. We hope you select the right size. Thanks for your cooperation.
Our NFL jerseys shop must have a jersey which you like. You can also
look other NFL football team jerseys such as NFL custom jerseys and
NBA custom jerseys, Jeremy Lin jerseys and so on online. Hope you have
a happy shopping from now. 2012,Go!

Subject: How to feed an existing folded dipole.
From: Tom Horne <hornetd@gmail.com>
Injection-Date: Fri, 26 Oct 2012 13:30:45 +0000
Content-Type: text/plain; charset=ISO-8859-1

I have a folded dipole coupled to the feed line with an Icon AH4 antenna coupler. That has worked rather well for me in my rather random pattern of operating. The folded Dipole is a Barker & Williamson BWD-90 from which I removed the Balun and the center resister. I then shunted the resisters previous location.   I had been feeding the modified BWD-90 with window line from the terminals of the AH4 coupler so as to allow the antenna to remain more nearly flat. With the weight of the balun, the terminating resister, and the coax on the center of the antenna it drooped quite a bit. I took out the resister because so many people told me that I would never know if I was getting a decent signal out or just warming up the resister. If I should not have shunted out the resisters previous location I would appreciate not just "don't do that" buy why it is a bad idea.

My problem is that I would now like to use a Yaesu FT-1000 that a fellow club member has loaned me and I have no way of controlling the AH-4 because the adapter that I was using with my Yaesu FT-857D will not work with the Yaesu FT-1000. I am open to any suggestions providing that they can be done in a yard that allows me only a ninety foot span between supports. I suppose I could save up and buy a new coupler but I was hoping for something a little less costly.

Should I give up on using the modified BWD-90 for now and put up another antenna? I could buy a fan dipole I suppose but I need a way to feed it that does not require a heavy balun up at the feed point if possible.

K someone please
--

Hi
Anyone know how I can make some RF chokes from ferrite bars? I have some
bars that are about 3/8" rnd diameter x 6" length. Are they suitable?

thnx

Hi
What is the best way to make RF ferrite style chokes from ferrite rods? I have some of those black 3/8" diam round solid by 6" length ferrite bars.

Any ideas?
Thanks

Hi
I got myself an old Alpha Delta DX CC now, it is old, very green. coils look green also.

I want to rewind those coils or even rewire the entire thing.

This is the 82ft no trap 80 through 10 dipole. Also includes 12, 17 and 30.

Any advice from the group? I see the coils are using a much thinner wire, new ones look nice and copper, this one is very green.

What size wire can those coils be? Can I just continue the copper length for the 80m leg and instead of separate copper winding just use the same copper and wind it around that winding core?

With the coil is the critical factor its length or number of coils?

Any advice from the group is greatly appreciated

73s

82' No Trap 80 thru 10 Dipole.And it is great ALL bands. This includes 12, 17, and 30.

Many of the chokes used to stop hash from switching power supplies use ferrite rods with a couple of dozen turns of heavy copper wound around the rods. Is this what you need?

I have the Ferrote Bars, just wondering what to do with them. Be nice.

I figured I could use them as some type of choke, wrapping them around the coax right near where I soldered it to the ladder line. This will keep all RF at the antenna and not bring back any.

But I use barefoot anyway, do you think it is necessary? I do not have an amplifier.

Just wondering if anyone has made any chokes this way.

Thanks

You need to know the material or the characteristics of the material to get a valid answer. "Transmission Line Transformers", by Sevick has some information on the subject.

I use old radio ferrites rods as RF chokes as it is easy to wind leads around them if there are connectors at each end. They are also easy to add in-situ and I have cured/reduced computer hash by creating chokes by winding leads around a ferrite rod. In another instance I had trouble with breakthrough on my Rotel amp when running 100W SSB on 40m. Winding each speaker lead around a ferrite rod near the amp output cured the problem.

Charlie.

There are a lot of variables here. Most of which I do not understand. I have enough experience to know that the number of turns in the coils is most important and the diameter of the coil is important. If you use the larger wire for the coils it will likely take a large coil form. You can certainly use the same wire for the whole antenna. I am just thinking that if they used thinner wire for the coils, you will not be able to get enough turns on the form to get the same inductance.

If I were in your place, I would use some insulated stranded #14 house wire for the whole thing. I would also buy some pvc pipe to allow the same number of coil turns (and same diameter). If it worked fine before you started this project, copying it wire length for wire length and turn for turn would be my plan.

Michael

Hi,
Yes you are very correct. The entire system apparently is working condition so why not just leave it alone. That is ok.

But it is 16 years in the air and very green, coils are green. When looking at the photos online the new ones while exactly the same design are beautiful copper with a clear protective wrap around those coils. Mine doesn't have that wrap and those coils are very green. The coils are smaller diameter wire, looking like the transformer wire with that sholack on it but then there are soldered connections back to the larger diameter bare copper green wire running to the insulators.

I would have to make another core if I were to wind the same new copper wire right from the center feed point to the ends of each leg. That would be basically the only difference other than instead of bare copper wire (new stuff) I have a big coil of solid copper wire with a jacket, I think it is 16ga. I was hoping to simply replace the exisiting bare green copper wire and the green coils with new copper wire with the jacket.

So do you think the changing of the coil wire diameter but keeping the same number of wraps is the way to go? Or because the new copper wire has the jacket, this will change the number of wraps if I measure the length of the old coil wire.

Lot of hardware in good shape on this old antenna, I just want to change all the copper.

Thanks for the advice,

73s

Hi
Ok, so you are talking about wrapping the feedlines around the ferrite bars, they are pretty thin, maybe even 1/4" or 5/16", I was thinking of wrapping the ferrite bars around the wire by breaking them into 1" lengths then line up about 4 of them and just tape them around the coax where it feeds into ladder line to stop rf from coming back and to ensure the antenna acts like an antenna.

I see ferrite chokes online for cheap price so I just get a few of them as they look solid (two solid halves) and they wrap around the coax.

Just thought I could use these bars but doesn't seem practical when they are so cheap for a half dozen of them online.

> I use old radio ferrites rods as RF chokes as it is easy to wind leads around them if there are connectors at each end. They are also easy to add in-situ and I have cured/reduced computer hash by creating chokes by winding leads around a ferrite rod. In another instance I had trouble with breakthrough on my Rotel amp when running 100W SSB on 40m. Winding each speaker lead around a ferrite rod near the amp output cured the problem.

Throw it away.

Make a dipole for the longest frequency you desire to operate on.

Formula is 33 / 66

Make the one leg 33% of the length of the frequency and make the other side so that when combined to the first leg equals 66% of the total length for the dipole.

A true Dipole is a half wavelength at the center cut frequency.

I use the term dipole loosely - because it is a non terminated antenna that has two sides...

It will then be resonant somewhere on all frequencies above the center cut frequency as long as the Q of the coil is high.
Don't use a low Q coil balun...

Any break at all in ferrite reduces the permeability quite a bit. Even
super gluing broken ferrite back together makes a noticeable reduction.

So, you idea won't work for what you are trying.

Paul, KD7HB

Thanks Channel Jumper,
but not sure which frequency I would most operate on. So with the tuner I have I want suitable access to as many as possible. I think rebuilding the DX CC is ok for what I want to achieve.

Do you know what is the critical points regarding those coils? I found out the copper wire coil I have is 12ga and solid, 300meters of it, it has a nylon jacket with a plastic layer around that. Regular industrial stuff.
So regarding those coils, could I simply replace that thinner transformer wire with windings of the same 12ga solid in jacket that will comprise of the rest of the dipole? Is it length of that coil's copper (badly oxidized) that is critical or is it coil turns? The present diameter of those coils is much smaller than the 12ga, so should I make new coils with that thinner transformer wire and make two solder connections there or can I simply weave the 12ga in its place? What would you recommend in this situation because I want to rebuild this good dipole with new copper.

Thanks

73s

I'm not sure if this will be helpful or wanted.

But your dipole antenna needs to be resonant - 1/2 wavelength on the
lowest frequency you desire to operate on.
Because most amateur radio frequencies are multiples of other
frequencies - 10 / 20 / 60 / 80 / 160
Some wavelengths will work with one antenna - as long as you do not try
to tune up on a non resonant frequency.

This is the problem with the G5RV
The ladder line is the matching network and it only works on 20 meters.
When you try to tune it up on 10 or 40 - it tries to damage the tuner -
arcing and heating.

At the same time, some will not be feasable - even with the tuner - such
as 12 / 15 / 17 / 30 / 60

It does no good to transmit if you cannot hear.

Not a good idea.

> I see ferrite chokes online for cheap price so I just get a few of them
> as they look solid (two solid halves) and they wrap around the coax.
>

I'm a recycle and reuse man :-) Also at HF you will need a few of the
clip-on ferrites for each lead as the impedance of one 'turn' will be
pretty low compared to a dozen or so turns a round a rod.

I made the G5RV and I am receiving a lot of RF in the shack. I also have
installed infloor heating in many parts of the house and while trying to
tune, I trip the GFI thermostats, I believe that is coming from the G5RV.
```

Channel Jumper mentioned that before that it was a dirty transmitting antenna. Now I am learning and installing ferrite rods (wrapping feeds from my power supply aound the 3/8" x 6" Ferrite Rods. I am going to wrap about 5 rotations and tape them up. Seems practically all I can do. Which is better? The ferrite bars to be wrapped around, at the ends of the feeds from power supply or the RF chokes that simply clamp onto the cable, two halves coming together? Any tips there are helpful.

Also, I landed an old Alpha Delta DX CC, now this was in the air for about 16 years and is very green. I want to rewire this antenna in hopes it performs best. My question is about those coils. Do I have to find the transformer wire which is smaller guage than the 12 ga wire I have to wind those coils? Or can I simply replace those green tranformer wire coils with the 12ga copper wire that I am using to replace all the legs of this fan dipole? I am just basically duplicating the dipole's engineering, but not the coils. I am wondering about those coils, do they need to have that shalac tranformer smaller guage wire with two soldered connections or can it be wound by the 12 ga copper wire and not have those two soldered connections. One wire for the entier leg and have it wound around that coil core.

What is the critical point here? The length of the wire or number of wraps on the 1-1/4" tubing they used? Or are they the same anyway? Would 50 coils of 12ga be the same length as what looks like 22ga? Same distance?

Thanks for the great discussions

Unfortunately that is not proof. Proof is when you compare a tuned dipole on say 75 and a 102 foot G5RV side by side with a switch to a simple 1/2 wave dipole. Actual testing like this is required. Mathematics and graphs are simply that, mathematics and graphs. Those little plots assume that there are no other variables that have not been considered or even discovered.

Every time I hear a poor signal breaking into our conversation on 75, and I ask what is their antenna? You guessed it, a G5RV. I always ask during any qso what antenna they are using and at what power.

No, it is not a design from hell. It is just a poor excuse for a multi-band antenna. A trapped multi-band dipole will work better from my experience and I don't like trapped multi-band antennas. The only antennas that sound weaker on 75 than the G5RV are the random wire antennas and a vertical using about 4 or 5 buried ground radials. So, the G5RV is a step up from those horrible antennas.

The G5RV is only gotten popular because it is cheap to buy and easy to erect. Performance is very difficult for most ham operators to ascertain because they have nothing with which to compare their G5RV. Many hams will give someone who is weak a 5/9 reading just to be congenial. They are not doing the other operators any favours doing this. I always give my peak s meter readings. This is certainly not a great standard, but is honest on my part.

So, Cecil, I think you need to erect a simple 75 meter dipole and a coax

switch. See what the other guys says about your two different s meter
readings on 75 meters. This must be done at different time of the day
and night a often. Keep a log of the results.

Michael

No need for me to do that, Michael, since Tom, W8JI, has already done it and reported the results. He had an A/B switch between a 1/2WL 75m dipole and a G5RV at the same height. He ran two tests:

1. He told the truth about which antenna he was using for the QSO. Most of the hams on the other end of the QSOs agreed that the 1/2WL dipole was superior.

2. He lied about which antenna was which. Most of the hams on the other end of the QSOs agreed that the 1/2WL dipole was superior. But since W8JI lied, they were really agreeing that the G5RV was superior. Were you one of those hams?:)

You can do this with a function generator (fast-edge square-wave pulses are what you want), possibly a resistive pad, a T connector, and a fast oscilloscope. I used this approach to test out and identify some poorly-labeled ham radio antenna cables at my city's EOC a couple of years ago.

Connect a BNC "T" junction to the oscilloscope's vertical input. To one side of the "T", connect a coax to a function/pulse generator that has a 50-ohm output (or use a low-Z generator and a 50-ohm series resistor pad). To the other side of the "T", connect the coax you want to test. Set the o'scope vertical sensitivity so that it covers 3-4 times the step voltage of the generator, and set the horizontal sweep rate to cover 2-3x the length of the coax you want to probe (figure 1 nanosecond per foot as a starting value, and triple it). Set the function/pulse generator for pulses that are at least twice the sweep length, and (if it's a pulse generator) a reasonable repetition rate (1 kHz or so). Set the scope for DC coupling, and set it to trigger on the rising edge of the pulse.

If the far end of the coax is open, and the coax is in good shape, what you should see during the sweep is an initial abrupt rise (to the generator's nominal output voltage), a flat trace for 2x the cable's end-to-end propagation time, and then an abrupt rise to twice the generator's nominal outut voltage.

If you terminate the coax in its characteristic impedance, the second rise won't occur (or you'll see just a tiny discontinuity at that point, if the termination resistor isn't an exact match). If you short the far end of the coax, the second rise will be replaced by an abrupt dive down back to zero.

Any wiggles or bumps in the first part of the trace (between the initial rise, and the reflection) will be the result of impedance discontinuities in the cable... damage, bends, connectors, conductor migration, etc. Measure the time delay between start-of-trace and wiggle, apply the cable's propagation-speed factor, and you can tell how far down the cable the discontinuity lies.

If you have a scope with dual sweep speeds and a sweep delay, you can "zoom in" on interesting sections of the trace and look at them in more detail.

If you don't want to lug a big pulse generator around with you, you can build a small one which connects right onto the front of your o'scope. A 555 driving a fast Schmitt-trigger inverter, a PIC with a fast discrete output-driver circuit... there are probably about a zillion circuits which would give a fast 50-ohm pulse that would work.

I actually have serveral. All you need is a pulse generator and a
decent oscilloscope. Pulse width and frequency will depend on the
length of coax cable you're trying to test.

These designs work well:
<http://www.epanorama.net/circuits/tdr.html>
<http://www.fccps.cz/download/adv/frr/Reflectoprobe/reflectoprobe.html>

This one is similar, but in my never humble opinion, not as good as

the previous one.
<http://www.mouthmusic.com/TEMP/aa6dd/Time_Domain_Reflectometer.jpg>

More:
<http://www.ecnmag.com/articles/2009/07/low-cost-high-resolution-time-measurement-application>
<http://www.youtube.com/watch?v=jOUhg07N2-U>
<http://www.youtube.com/watch?v=Il_eju4D_TM>
etc.

Also look on eBay for a Tekronix 1502, 1503c or similar TDR.

I tried to buy one and was stung. Was told to send a Western Union payment =
and he reckons it never came, so $230 odd Australian. He virtually said in =
email he didn't receive the payment (told me himself it will be that day) a=
nd has written the transaction off the books. So, I'm down $230 odd for the=
 experience and he won't return my emails now.

Steer clear of the so called TAK-tenna site, you won't get your antenna. So=
, all in all, can't tell you how it works.

That's not going to happen with my home made TDR. The speed-o-lite is
about 1ft per nanosecond. To see 0.1 inches, you'll need a resolution
of:
   0.1in / 12in/nsec = 8.3 picoseconds
That can be done, but not with commodity hardware.

Have you measured or swept this antenna for the resonant frequency?
PVC pipe has a velocity factor of about 0.9 which will move minimum
VSWR point down in frequency.  The amount varies with the diameter and
thickness of the PVC tube.  The J-Pole antenna has a wide enough
bandwidth (about 10MHz for <2:1 vswr) that some change in tuning can
be tolerated, but I think a ham antenna tuned to 135Mhz is rather
tacky.

True, for most parts of the sky, except for directly overhead where the GP has a big null. You should get about 3dBi from both the GP and QFH antennas. The difference is that the QFH will not have any cross polarization losses, while the ground plane automatically has a -3dB loss from the conversion from RHCP (NOAA-19???) to linear vertical polarization.

>I have built according to plans,
>it is clockwize rotated and everything looks ok.....

According to what plans? Post the URL for the plans and a photo of your construction, especially the phasing sections. If there's any difference, someone will spot it.

>I use the same coax (switch antennas), but still, it won't work.

Hopefully, you don't have both antennas connected at the same time.

>Is there something I have missed??

Yep. What bird you're listening to, URL of construction article, numerical measurements of signal strengths, methods of comparison, mounting, lengths of coax cables, antenna pre-amp location, system description, etc.

Deja Vu. The last time I troubleshot exactly such a system, I found that the receiver supplied 5V bias for running an antenna mounted RF amplifier. The QFH antenna appears as a short across the antenna connector which clamped the 5VDC to ground, causing the pre-amp to act comatose. Running the system on a bench test looked perfect because the shorting antenna was disconnected. Adding a coaxial capacitor isolator between the RF amp and the antenna connector fixed the

problem.

Hint: That what is mostly obviously correct, beyond any need of
checking, is usually the problem.

>Do you think we have discovered one way shingles ???

Nope. You've discovered Fresnel zone diffraction, multipath
cancellation, and frequency selective fading. Congratulations.

> Anyone else seen anything like this ?

Not on 6 meters, put plenty at 900MHz and up. Basically, if you have more than one path between endpoints, and the path lengths differ by 1/2 wavelength, you'll get cancellation. It's easy enough to detect the problem by simply moving 1/2 wavelength toward or away from the other endpoint and see if the signal levels change significantly. If you can't do that, change frequency by the largest amount possible.

Also, if you live 15 miles apart, with antennas at about 15ft off the ground, you're below the horizon. That means you're relying on knife edge diffraction to communicate. That works, but is not reliable as almost any metal object near the knife edge can send the signal off into the wrong direction. At 6 meters, things like swaying wet trees can do that. If the signals are NOT stable and tend to move around in the wind, this might be the problem.

One way paths are possible. It's not the path. It's the antennas. The basic assumption is that the antenna pattern is the same in xmit and receive. That's a fair working assumption but not always true. Different side lobes of an antenna can have a slightly different phase shifts. If the two multipath signals arrive via the main lobe and a side lobe in receive, and the side lobe moves slightly in transmit, it's possible to achieve cancellation only in one direction.

If the 6 meter receiver has a noise blanker, he could be hearing so
much noise that the receiver acts like there's nothing to hear.

>Steer clear of the so called TAK-tenna site, you won't get your antenna. So, all
in all, can't tell you how it works.

Retributive justice, your nemesis.

I once ordered a direction finding antenna from USA  for 100$
plus 50 $ postage plus 20$ customs, and all I got was some bent wire
with loose connectors. The coax cable was not even soldered or
crimped on the BNC central pin!

I am Austrian, the other guy is Australian, not far away :-)
Ceterum Censeo, USA must be punished.

That antenna is simply $30 worth of PVC pipe and wire. Don't hams homebrew
anything anymore?

My fault. I'm using Thunderbird and they added an additional button when
I last updated. They now have a "Followup" button to which I have not
yet become accustomed. It was always "Reply" before this last update.

I apologize for my confusion.

John

Note the date above.  This is a recycled old posting, posted by some
moron who gets his jollies reposting old messages.

Many hams don't homebrew. They do not have to tools to do things like hams of the past.

It is often cheaper just to buy something already made. Say I was going to put up something like the G5RV. I have to buy some wire. The wire is just over 100 feet. That might mean buying 500 feet on a roll or ordering it with the postage. Then need some ladder line. Need about 35 feet. Have to get either 50 or 100 feet if I can find it locally, probably not any around now as most TV sets use cable or coax. Also insulators and coax to locate. Things start to add up. Or I could get it all in one 'kit' for much less.

Not all hams have a place to store supplies or build things that are large. I sometimes build and sometimes buy. I just bought something to program some radios off ebay. It was a circuit board with the parts on it. I did have to put it in a box. The board only had 1 IC and a few capacitors and leds on it. Two boards shipped was only $ 7.99. The shiping could have more than that at some places. I was going to order a VHF preamp kit but the postage put me off. They wanted $ 12.00 for postage. I could have put 50 of those kits in the $ 5.50 UPS mailing box. The kit was about the same as the postage.

Excuse my pedantry, but -3dB loss is actually a 3db gain.

How come nobody recommended the W5GI Mystery Antenna?

Many websites claim it to out perform the G5RV antenna and simple construction.

I have to make one, any comments on which is better or worse? Have you folks had luck with either or dissasterous results with one or the other? Is the double boozooka better?

Thanks for any comments.

The construction is not as simple as the G5RV. Then there is the added cost and trouble to go to for the coax in the antenna legs.

I do not see any simple dipole really doing much beter than another in all directions. If you are lucky the antenna will be positioned so some of the gain will be in the desired direction. If not so lucky , then the antena will not work very well for you.

As long as the feedline is not very lossey and at the feed point the antenna has a low SWR, all around I still doubt that any antenna near the same length will be beter all the time.

http://vk1od.net/antenna/W5GI/ has an interesting analysis. The conclusion seems to be that this antenna is basically similar to a G5RV, and that many of the developer's claims seem to be unsupported by actual measurements.

As I understand it, this antenna and the "double bazooka" both use coaxial elements within the dipole section... variously described as "resonators" or "phasing stubs". In each case, it looks as if these coaxial stubs do contribute to the antenna appearing to be somewhat more broad-band than would be expected of a simple doublet of the same size... but that this broad-banded behavior is the result of losses in the coax sections (either dielectric loss, or I2R loss in the conductors). The Barker and Williamson broadband folded "dipole" is somewhat of the same ilk... it's convenient to drive due to its relatively flat SWR, but this is achieved at the cost of having a lot of the RF power end up as heat in the termination resistor assembly when the doublet itself is being driven far off-resonance (which is much of the time, in multiband applications).

There's quite a lot of anecdotal support for the W5GI, the G5RV, the B&W, and the double bazooka - a lot of people are happy with them - but well-documented measurements don't seem to support the idea that there's anything magic or unexplainable about them.

If you'd care to build a W5GI, and compare it "apples to oranges"

with other antennas of a similar size and report some measurements,
I'l sure we'd love to see your results!

I've never tried one. And it's been so long since I looked
at the plans for it, I forgot exactly how it's built.
I know W5GI.. Used to talk to him on 40 about 20 years
ago. But I can't remember if he used that at that time or not.
I don't use the Bazookas. They are slightly more lossy than
a plain wire dipole. So never saw the point.. And they are
heavier too. Takes stronger supports.

Hi OM Jeff,

You are absolutely correct.

I have checked both the antennas in the range 140-150 MHz and find that
the J-Pole has minimum SWR at 145 MHz and the Slim Jim at 143 MHz.

Many thanks.

73

Nandu.

"This design is unusual as the coil is not part of the radiator."

The base-matching coil on a 5/8WL doesn't radiate much because, unlike the base-loading coil on a 1/4WL, it is not located at a current maximum point which is located 1/8WL up from the feedpoint.

You can get all 40+ years of 73 magazine at:
<http://archive.org/details/73-magazine>
<http://archive.org/search.php?query=collection%3A73-magazine&sort=-date&page=1>
The Aug 74 issue is at:
<http://archive.org/details/73-magazine-1974-08> (33MBytes)
See Page 63. A steel rod for a whip antenna? I don't think so as
it's rather lossy:
<http://vk1od.net/antenna/conductors/loss.htm>

I'm also not so thrilled with the center tapped matching network. I've
taken apart several 5/8 wave loading coils and always found the coax
tap close to the ground end. The impedance of a 5/8" wave monopole
over a ground plane is probably over 500 ohms (too lazy to fire up
4NEC2 and check). For a 50 ohm coax feed, that would be an impedance
ratio of:
   500/50 = 10:1
which is a turns ratio of:
   sqrt(10) = 3.2:1
Move the 50 point closer to the ground end of the coil and maybe it
will work better.

I do not recomment 5/8 for mobile car 2m usage.
I had one and in the park garage the antenna would scratch along the
ceiling. When I did not pay attention, it would smash the fluorescent
lights. I had to drive in zigzag to avoid them (had a small car)
Driving fast, the antenna would bend down to horizontal like a straw.
Driving slowly, the antenna woud swing to and fro, and cause
horrendous additional fading.

There is only a theoretical gain over a lamda/4 and only a very small
one which you will never achieve in real world.

w.

Subject: Wire antenna feed-line questions
From: gipy <gi1pi@yahoo.com>
```

```
Injection-Date: Sun, 14 Oct 2012 22:04:25 +0000
Content-Type: text/plain; charset=ISO-8859-1

I am using a long wire in the trees coming straight to my tuner but I need to
route the feed line underground to keep it stealth and I can't seem to find any
articles on this topic.
My question...
I would like to use insulated wire or does it have to be coax only and would I
lose performance?
Someone told this type of antenna would act as a lighting rod and would be
dangerous.
My other question...
Why would it be more dangerous than any other antenna  when most receivers and
transceivers are grounded in some way?
Thanks in advance

Well you cannot bury open wire and expect any results. What frequency are you operating on? Are you transmitting? I think your best bet at this point is to bury coax and feed a dipole antenna if you are transmitting. Random wire antennas perform even worse than G5RVs. They are about the worst.

I have a 5/8 wave Maxrad on my Subaru Forester. If I hit anything, the spring will prevent damage. If I hit something hard, the mag mount falls off.

I've heard the broken fluorescent light story and find it improbable with a thin flexible antenna. Many years ago, I did manage to break an overhead fluorescent tube with a 102" whip antenna and a running start. It took me about 15 tries to break it. Actually, I'm not even sure if the antenna broke the bulb as one witness said that it just fell out of the socket.

Take a fish scale, measure the force that can be obtained by bending back a 5/8 wave 2m antenna. I have no clue where my fish scale is hiding so I can't do the test. Next, take a string or wire and wrap it around the middle of a fluorescent tube. Pull on the wire with the same force as the antenna bending. I'll wager you what's left of the Ramsey CT-2000 frequency counter that I just blew up by plugging in a positive ground charger, that the tube won't break.

>There is only a theoretical gain over a lamda/4 and only a very small
>one which you will never achieve in real world.

<http://www.arrl.org/forum/topics/view/91>

Length	gain,	angle,	gain at 10 degrees
1/4-wave	0.4 dBi	23.5 degrees	-1.6 dBi
1/2-wave	0.6 dBi	17 degees	-0.4 dBi
5/8-wave	0.5 dBi	13.5 degrees	0.2 dBi
3/4-wave	4.7 dBi	46.5 degrees	-3.0 dBi
1-wave	4.7 dBi	32 degrees	-3.7 dBi

That's about 3dB (including the matching network losses) or twice the gain of a 1/4 wave whip. My personal experience with our local 2

meter repeater is that I can use the repeater effectively with a 5/8
2m antenna, but not with a 1/4 wave antenna.

I'm not sure I agree with that statement, I have used a g5rv in the past and I have had great success throughout the years with a random wires, end-feds, long-wires etc. The trick is to have a good ground when using a random wire.

Im in a situation where I need to bury the feed-line to a random wire (end-fed type) antenna and Im looking for the best way of doing this.

If you came here for advice why are you arguing with the first person
that responded?

Just go ahead and do what you (mistakenly) think is true just because it
seemed to work OK.

And it's "I'M" not "Im".  At least learn the language you speak.

tom

Wow, a newsgroup cop and an English teacher!

BTW it's I'm and not I'M, but I won't tell you to learn the language you write.

I very much respect and appreciate the "first person's" opinion and my apologies to him for not expressing that before but it is just that, an opinion, just like mine. I did not think a difference of opinion could be called an argument.

My disagreement "not argument" really had little to do with my question about burying the feed-line, not which antenna works best.

I am pretty sure by now this thread has gone south thanks to your watchful eye on correctness, sensitivity and diplomacy on this group but anyway,
I would still like to hear from anyone with some advice on burying a feed-line.

> Thanks in advance

You can not burry a single wire feed to a long wire. When the wire leaves the transmitter/tuner it becomes part of the antenna. If you have to use a long wire and a burried transmission line, you need a remote tuner and go from the transmitter to the tuner with coax. Even if you use open wire/twin lead for the transmission line, you need to keep it several inches from the dirt. Almost impossiable to do. It will not make any differance if the wire is insulated or not if it is under ground.

No. not a newsgroup cop, just wondering why the first response to you was disputed. And I held the cap key down too long. It happens.

He's pretty much on the nose though in his comments. If you can make a
G5RV or random work, it's mostly luck. Yes, with end fed proper
grounding helps a lot, but it's still a crap shoot.

As I understand it, the modeled gain of a 5/8 monopole over a 1/4
monopole, usually includes the assumption of an infinite ground plane.

The body of a typical car isn't large enough to act as a good
approximation of an infinite ground plane at 2 meters. If you
actually model a 5/8 monopole over a small ground plane such as a car
root, you'll likely find a not-very-nice-looking pattern... the gain
lobes tend to "squint" away from the horizontal and you lose much of
the theoretical gain advantage of this antenna.

Revision: 1.2 2011/11/02 04:08:53
Posting-Frequency: posted twice monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35f23326

```
the rec.radio.amateur.moderated Moderation Team had decided to consider       |
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup.  After a successful trial         |
period (90 days, through early July 2009), we decided to adopt this           |
change permanently.                                                           |
```

Approved rec.radio.amateur.* newsgroups are those that are currently listed in the latest version of the "List of Big Eight Newsgroups" which is crossposted monthly to news.announce.newgroups, news.groups, and news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those that have been created consistent with the suggestions in "So You Want to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either "radio.amateur" or "ham-radio" in their names, including uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved newsgroups up-to-date. In case we have overlooked any, and a submission is rejected in error as a result, the rejected submitter can E-mail us at our administrative contact address (in the signature at the bottom of this article, and the default Reply-To for the rejection message) requesting that it be added, and that the article be approved. We may still choose to reject articles crossposted to any alt.* newsgroup with an inappropriate name, including obscene language, embedded name-calling, or encouragement of unlawful conduct.

Please direct any comments, questions, or criticisms to
rec-radio-amateur-moderated-request@panix.com.

Probably depends where you mount it though. All the times I've
compared the 5/8 vs the 1/4, the 5/8 would be superior to farther off
stations. But.. I always planted the antennas in the middle of the car
roof. In the real world, I found the 5/8 did the best on far off
stations, which tends to confirm some gain over the 1/4 was there
at the lower angles. The 5/8 also tended to picket fence less.
Me thinks the roof and supporting pillars tends to provide a fairly
decent lower element for the 5/8. Or at least good enough that most
people that try and compare them will go with the 5/8.
There are some instances where the 1/4 might be better though.
Say if you were down in a valley, and the repeaters are way up high,
fairly nearby. The broader pattern can sometimes work better in that
case.
With the height of my usual HF antenna, the height of the 5/8 2m
antenna on the roof was never an issue.. lol..
Anyway, I always achieved some of that gain in the real world.
And ditto for most 5/8 GP's at the house vs 1/2 and 1/4 wave
antennas. The 5/8 always won to the farther space wave stations
across town despite the theoretical issues.

The situation described certainly does seem to be one where a remote
automatic tuner would be the best solution (plus a good ground, of
course). To minimise interference problems to-and-from the domestic
electrics, it would normally be better to locate the tuner at the far
end - although this would entail having a longer run of coax.

Hi OM Dave,

In my experience a ground plane antenna, whether 1/4&#955; or 5/8&#955;
, scores over other 'horizontal radiating' or 'gain' verticals when the
signal has to go over terrain to work distant repeaters.

Many thanks for your views.

73

Nandu.

And make it an inverted L while you're at it! I'm just about to order an
SGC239 auto ATU for my inverted L (www.radiowymsey.org/invl.htm). My coax
lies on the ground but only because half the garden is patio and steps.

Charlie.

Getting a G5RV or a 'random' wire to work isn't 'mostly luck'. It's more
a question of simply knowing what you're doing.

Hi tom,

I have been a ham since 1955. I have experience trying different types of antennas. At one point (10 years) I designed antenna installations for Raytheon Co.

Those who have not compared their random wire or G5RV to a good antenna figure it is working just fine.

I can say that I know that if you want a dipole to work on multiple bands, it needs to be a full 1/2 wavelength on the band you want it to work on. Feeding it with open wire and a tuner will allow some decent performance on bands that are higher in frequency. I am guessing Tom that you already know this.

My favourite antenna for living in the city on a lot surrounded by homes and industry is the horizontal loop fed with open wire. This does a great job of nulling horizontal noise from the town.

Many hams just look at the 102 foot spec for a G5RV and works all bands and say great. If they can talk to anyone they figure it must be perfect. It is not actually a bad antenna on 20 meters. However, the performance on 75 is abysmal. I work 75 most of the time and when I hear a new guy come on in our area with a weak signal we all figure the guy is running a G5RV. This is usually the case. We always nudge him in the direction of putting up a decent antenna.

The only time a random wire makes any sense is aboard ship or boats. If you can make a solid connection to the sea water you have a decent antenna. BTW a decent connection on a non steel or aluminum vessel is 30 square feet of copper plate on the outside of the hull.

It is hardly worth my time to talk with anyone who already figures he knows all about antennas because he has used a G5RV and it works fine. We need to reserve our comments about what really works for those who are actually interested in improving their station operation and have not taken the attitude that they are already experts. :-)

There is a guy here my age who has experimented with antennas much more than have I. He nudged me into changing my 450 plastic dialectrict balanced line to my loop to an open wire. I did not expect much difference. I was shocked at the improvement. He is our resident expert in the "North Woods". This is the Michigan upper peninsula, Northern Wisconsin, and Minnesota. He is not an expert on antenna theory or math, but damn sure knows what works best. I wish I had changed my feed line three years ago when he told me to do so.

Michael

I am in a situation where I HAVE to bury the feedline, there is no other wa=
y around it. I have trees about 20 feet away from my home in the back, grea=
t for swinging a long wire, dipole, whatever works but being that the actua=
l space between the trees and my home is a common area, I have to bury the =
coax.=20
Placing a remote tuner on the other side would be a bit of a hassle but I s=
ee its starting to look like the only way to go?
I got plenty of time, I just want to do this once and the right way.
Again, any thoughts appreciated and thanks to all who have posted, it is tu=
rning out to be a very interesting thread.

It looks like you will have to use either a remote tuner, or something you
can feed with coax.  Maybe a trap type of dipole.
While I have no idea how they would work, you may want to check out some
from DXS Engineering.
http://www.dxengineering.com/search/department/antennas

For some of the low bands I use a homade OCF antenna patterned after the
Carolina Windom. But I also have other antennas up for some of the bands.

Would you please itemize the losses and radiation patterns that explain why you
believe that to be true for 75m?

Live in the Minneapolis metro and just got back from the lower peninsula last Monday. Was camping next to the lake in West Olive. Used my usual portable HF antenna, a 20m end fed. I also have a 40/20 end fed, but didn't figure it was worth the trouble for this trip since I was going to be busy with other things at the site and I didn't know the campground.

You probably know the rule here - if you put it up at 20 below it will never come down.

I'd prefer to run the ladder line the whole way from the tuner
to the antenna. I see no benefit to using the twin coax section,
as it will act the same, except with larger conductors.
And I've never been a fan of coax/choke/ladder line feed line
schemes. I've never seen any real problems from having ladder line
near other metal or wires as long as they are not parallel for
any long distance. Short distances such as a ladder line crossing
a metal window frame that's close on it, seem to have very little
overall effect.
From a feed line and system loss point of view, using all ladder
line, and the minimum tuner inductance needed to get a match would
be the best way to go.
And like Cecil said, whether an antenna is resonant or not means

very little as long as you can get the power to it without it
turning to heat.
Even a short 1/10 WL dipole would radiate nearly all power applied
to it. If you can get it there intact... :/ That's the trick.

I use resonant dipoles, but it's not because of any special
property with the antenna itself. It just happens than it
makes it very efficient and convenient to feed directly with
coax. I need no matching, so I have no matching loss.
The only real system loss I see is the loss per foot through
the coax feed line, which will increase with frequency.
On the lower HF bands, coax is quite low loss per foot, so
my overall losses will be quite low, even with RG-58 at
reasonable lengths.

Ladder line is handy as it's losses are still usually fairly
low even with a high SWR. So usually most of what comes out
of the tuner, makes it to the antenna.
This will often not be the case with the coax/choke/ladder line
schemes. :(

Chokes made from coax are limited in frequency range.  There was a link
to an application that gave the specs for a coax choke provided by one
of the people here once upon a time.  I'll see if I can dig it up.

Posting-Frequency: posted twice monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35f23326

the rec.radio.amateur.moderated Moderation Team had decided to consider |
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. After a successful trial |
period (90 days, through early July 2009), we decided to adopt this |
change permanently. |

Approved rec.radio.amateur.* newsgroups are those that are currently listed in the latest version of the "List of Big Eight Newsgroups" which is crossposted monthly to news.announce.newgroups, news.groups, and news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those that have been created consistent with the suggestions in "So You Want to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either "radio.amateur" or "ham-radio" in their names, including uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved newsgroups up-to-date. In case we have overlooked any, and a submission is rejected in error as a result, the rejected submitter can E-mail us at our administrative contact address (in the signature at the bottom of this article, and the default Reply-To for the rejection message)

```
requesting that it be added, and that the article be approved.  We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.

Please direct any comments, questions, or criticisms to
rec-radio-amateur-moderated-request@panix.com.

A good example of an efficient non-resonant antenna is an EDZ, extended dou=
ble Zepp. I modeled a 20m EDZ with EZNEC. It has a feedpoint impedance of 1=
75-j1000 ohms, clearly non-resonant. Using 10.3 feet of open-wire line as a=
 matching section, the SWR on the coax to the shack is 1.1:1. The EDZ has =
3 dB gain over a resonant 1/2WL dipole in the direction of the dipole's max=
imum gain.

Why is this non-resonant antenna so efficient? First, because it is a low-l=
oss antenna system. Second, because it has a near conjugate match at the fe=
edpoint. If one terminates the matching section in 46 ohms and measures the=
 impedance looking back from the antenna feedpoint one will measure very cl=
ose to 175+j1000 ohms.

Non-resonant antenna feedpoint of 175-j1000 ohms with an impedance looking =
back down the transmission line of 175+j1000 ohms. That's the formula for m=

```
aximum transfer of available power from the source to the load. The non-res=
onant antenna length doesn't matter because the entire system is resonant.

The EDZ is non-resonant without a feedline. Strangely enough, a 1/2WL dipol=
e with an insulator in the middle is also *non-resonant without a feedline.

Boomer;796886 Wrote:
> test

I posted this previously on another forum, but for the sake of arguement
I will post it again...

I will use a very easy example, KDKA Pittsburgh AM 1020
They built a tower 718 feet (218 meters) tall and fed it with tens of
thousands of watts of power..
This allows anyone with a simple receiver to receive their signal with a
antenna 32 - 36 inches long, even in Daytona Fla when they were still
running the old Westinghouse transmitter 50 KW...

When you use a compromise antenna - something that you have to force the power into, or use a antenna tricker to make believe that all the power generated is being applied to the antenna - you can also make beleive that it is receiving all the signal in the atmosphere.

Unless the people you are talking to is very strong, you aren't going to hear them.. All goes back to the KDKA 718' tower and it's 50,000 watt transmitter.

Unfortunately - I ran across some morons the other night on 40 meters that was of the same opinion.. They were all using non resonant antenna's, tuners, and amplifiers.. Their signals were 20 / 9 or more and they were all proud of themselves that they could hear each other and that their signals were so strong..

On the other hand, I was using my Barker & Williamson BWD 90 antenna / 20' off the ground with 100 watts and they claimed that they could not hear me or hear me well.

They started acting like silly CB'rs and refused to adknowledge me..

When I informed them that they were not suppposted to broadcast and that Part 97 rules says - you should use the LEAST amount of power to transmit and not the most - they got offended.

Well I have a 200 watt transceiver and I don't use any amplifiers and I don't use any antenna tuners and I never need more then 100 watts to talk to anyone. If I can hear them - they can hear me!

I wasn't going to brag, but I let it slip that it was the new Kenwood TS 990 and they started howling.. Something about it not being part 97 approved and that it was not for sale yet..

I never said I bought it, I just said I was using it!
Cranking it up to 200 watts - wasn't going to make my signal any louder or stronger. We all know it takes 4 X power increase to get 1 S unit on the other persons receive...

A G5RV SUCKS!
It talks and receives on 20 meters and is a compromise everywhere else...

A Dipole antenna is 1/2 wavelength long and is a balanced antenna.
When one wave is in phase on the one leg it is out of phase on the other leg.
The two equals out and the antenna is resonant.

There are offcenter fed dipole antenna's that are multibanded - but they require a balun / torroid coil which is special wound and checked for tolerences which are not normally checked with commercial grade baluns.

YOU PAY EXTRA FOR IT!

Sorry, that is false for most modern transceivers. If a transceiver is desi=
gned for 50 ohms (most are), when the system is conjugately matched with a =
50 ohm Z0-match, transmitting and receiving are reciprocal, i.e. the system=
 is conjugately matched (and resonant) on both transmit and receive. That m=
eans, in either direction, a low-loss system is transferring the maximum av=
ailable power.

You can prove the above for yourself. Choose any system and adjust it until=
 the transmitter sees 50 ohms. Disconnect the transmitter and install a 50 =
ohm dummy load at that point. Then go anywhere in the system with a grid-di=
p-meter and you will find resonance. Note that if one gets a dip on a GDO w=
hen coupling it to the antenna wire, it is working just as well on receive =
as on transmit.=20

> The two equals out and the antenna is resonant.

As I said earlier, a 1/2WL center-fed dipole is non-resonant without a feed=
line. An EDZ is non-resonant without a feedline. There's no difference.=20

To prove my point, it is recommended that to de-tune guy wires and keep the=
```

m from radiating, insulators be installed every 1/4WL which makes each 1/2=
WL look exactly like a 1/2WL center-fed dipole with no feedline. Even in al=
legedly resonant antennas, the feedline is the thing that is resonating the=
 system.

Excellent discussion. Thanks for all the expertise. I am still reading and
learning and I take what you folks type and google it and read more about it
and learn it. A lot of what you are saying immediately goes over my head, I
am not an idiot, my master's degree is in another field, my graduate is in
another field, and my undergrad and even college are in another field.

Electronic theory is difficult to understand without the foundation you folks have, I am learning it and it is obvious you folks are well informed and knowledgable about antenna theory. Excellent discussion and thank you all so much for having it becuase I benefitting from it.

I am thinking that my best bet for a single antenna, dipole is the Bazooka? I don't want to have an array, or 3 seperate fan dipoles, or a back yard full of wiring as I am in a windy neck of the woods, property is very small also. The G5RV fits nice, now it has feed with 50ohm coax, I removed the ladder line from going through the wall and traveling along side a few other wires and replaced it with 50 ohm coax then meets the 450ohm ladderline (only one inch separation between the two coated copper solid wire ladder line). No choke or balun then exactly 30.6 feet of ladderline then 102 feet at the top. At about 40 feet in the air. Using the MFJ 2kw tuner and an old 1970 solid state transceiver, what better can I do? Without buying big.

But I love the depate we are having here on best and most suitable dipole for all bands, now lets hear some suggestions (clean) and recommendations. What is the best home made dipole antenna that I can tune to with this tuner, 10-80, barefoot, (I work code a lot) , clean, buildable, and hangable, it has to go over a couple trees which is no problem but if the wind starts spinning it and I have to keep climbing, too much maintenance.

Thanks again

73s

However, in your example, the KDKA tower is not used for receive. The tower is used for transmit, and some marginally effective antenna might be at the receiver.

If the antenna reciprocity theorem is assumed as correct, wouldn't a ham radio antenna be just as "good" on receive as on transmit? And when the transmit conjugate match is achieved, the transmit efficiency can be pretty good. (subject to the size of the mismatch and the quality of components, including feedline).

I'm tuning a Cushcraft AP8 3,5-28MHz trapped vertical.
I check VSWR using both a MN2700 Drake Matching Unit that a MFJ259b
analyzer. At the same connector readings are very similar on all
frequency except on 10MHz.
On this band, 10.100MHz, MFJ259b shows 1:2,1 VSWR while MN2700 shows
1:6 VSWR. I replaced the MN2700 with a Daiwa CN801 which confirmed the
high 1:6 reading to me.
Why shows the MFJ259 analyzer an incorrect reading on one band only ??
Many thanks

A Bazooka is a ton of hassle for almost no improvement over an ordinary dipole,
just slightly wider bandwidth. For HF it's hard to beat a 130 foot dipole fed with
~100 feet of ladder-line through a good 1:1 choke on the output of a good tuner.

A G5RV is a good antenna for 80m, 40m, 20m, and 12m operation but also requires a
tuner.

Why the 100 feet of ladder line? All I can do is 35 to 45 feet of ladder line? Now I am at 30.6 feet of ladderline with 102, The ladderline and coax now is fitting in its space, I could increase the spread to the 130 feet on next dipole if that improves the ability to tune it for lowest SWR through the MFJ989C Tuner. I think the tuner is big for barefoot operations. As I am having more difficulties now, the old solid state transceiver I am using has sat for so long without operation it barely pumps out 10 watts. A friend told me moisture must have took its place in some components and to leave it on for a couple days and I am noticing a bit improvement after one day so because the rig sat for so long without operation I think it needs to see a servicing doctor. I will leave it on for a couple days to see if it heals itself as recommended. Or I see there are new rigs available from 2m to 160, all band, all modes, and only about 12,000 dollars. No, I will hope this one recovers. There is no way I can pay anything like that. No way.
Thanks again, 73s

My guess(tm) is that there's something wrong or blown in your MFJ259b. However, I can't tell if the VSWR meter in the Drake MN 2700 antenna tuner is any better. A third VSWR meter, of known quality, would make the determination.

First, check the MFJ259b with various known resistive loads.

1:1	50 ohm
2:1	100 ohm
2:1	25 ohm
1.5:1	75 ohm
etc...	

A leaded resistor crammed into a PL259 will not do because of excessive lead inductance. Use chip resistors or commercial loads. A T connector with two loads is handy for less than 50 ohms.
If your readings are not fairly close to the theoretical value, it's time for a repair job:
<http://802.11junk.com/jeffl/MFJ-269-repair/>
and/or a calibration:
<http://www.w8ji.com/mfj-259b_calibration.htm>
See bottom of page on how to build calibration loads.

Calibrating the Drake MN 2700 VSWR meter might be tricky. It's designed to operate a high power levels and does not appear to have a shielded VSWR section. Too much RF floating around the tuner and the VSWR meter directionality will be affected, resulting in an inaccurate reading. Since there's probably no calibration or adjustments, and the unit is obviously not going to work with low power resistive loads, I would simply try a 50 ohm dummy load and two dummy loads on a T connector, to see if it reads correctly on a straight through connection. Another method is to take a third VSWR meter between the xmitter and the MN 2700. Keep the coax connection very short between the meter and the MN 2700 to keep coax cable lengths from affecting the readings. Use a double male PL259 "barrel" if possible.

These days I am doing a service my mobile station installation (VHF/UHF
FM mode). What about to use a RF choke (ugly) balun at the feed point of
antenna? (diamond NR-770s).

You are so right Channel Jumper,

The G5RV is a piece of s&%$ on any band but 20 meters. They are
notorious for poor performance. They are only sold because they claim
multiband performance.

If you want an antenna that works well you must look elsewhere.

BTW, I talk with a group on 75 daily. We have a regular round table.
When someone jumps in with a very poor signal we always ask them what
they are using for an antenna. The answer is that they are mobile or are
using a G5RV.

OK, yes they work if you count operating your transceiver with an antenna that radiates on 75 about as good as a bed spring.

Michael

A 102 foot dipole is an efficient radiator on 75m with a feedpoint impedanc=
e of 36-j325 ohms on 3.8 MHz according to EZNEC. According to the transmiss=
ion line loss calculator at:

http://www.vk1od.net/calc/tl/tllc.php

the G5RV feedline system has about 0.6 dB higher loss than a 75m dipole fed=
 with an equal length of RG-8x. So the G5RV is about one tenth of an S-unit=
 down from a 75m coax-fed dipole. Can you really detect one tenth of an S-u=
nit difference with your ears? One tenth of an S-unit is virtually impossib=
le to distinguish on most S-meters. It is generally accepted that one dB is=
 the smallest difference detectable by human senses.

W8JI ran some interesting A/B tests involving a G5RV vs a 75m dipole on 75m=
. Most hams agreed that the dipole was better. Then Tom ran the same A/B te=
sts but lied about which antenna was in use, i.e. he said it was the G5RV w=
hen it was really the dipole - and vice versa. Most hams agreed that the di=
pole was better even when the "dipole" was actually the G5RV.

> Why the 100 feet of ladder line?

When feeding a 1/2WL dipole, one needs to use about 1/2WL of ladder-line to repeat
the low feedpoint impedance at the tuner. If one uses 1/4WL of ladder-line, the
impedance at the tuner will be about 4000 ohms.

If you are happy with the G5RV, I would suggest sticking with it.

That's using the usual "commercial" version though. I wouldn't use one of those either. The tv line/choke/coax is the problem, not the antenna. If you use ladder line the whole run from the tuner to antenna, they will perform much better. The tuner setting can be critical too. You must use the least inductance required to get a usable match if you want the least loss. I tested this one time, and the loss could vary almost from nearly unmeasurable using the very least inductance, up to an easy

20% loss if you used too much.
In my case, I was using a 989C with a roller inductor, which lets me
use the very least inductance.
If the inductor is tapped, there may be some compromise, but you still
want to use the lowest value tap that will match.

Saying all that, I use full size dipoles in parallel fed with coax..
But I'm not expecting to work all bands, even though I can with a
tuner. I'm on the higher bands so little, the hit doesn't bother me.
I've got a tower and yagi if I really wanted to get serious about those
bands.. But.. they collect dust in the garage and attic.. I'm on
160/80/40 most all the time.. I like 30m, but with 40/80 dipoles, using
a tuner to band aid it to 30m works fairly well.

an equal length of RG-8x. So the G5RV is about one tenth of an S-unit down from a 75m coax-fed dipole. Can you really detect one tenth of an S-unit difference with your ears? One tenth of an S-unit is virtually impossible to distinguish on most S-meters. It is generally accepted that one dB is the smallest difference detectable by human senses.
>
> W8JI ran some interesting A/B tests involving a G5RV vs a 75m dipole on 75m. Most hams agreed that the dipole was better. Then Tom ran the same A/B tests but lied about which antenna was in use, i.e. he said it was the G5RV when it was really the dipole - and vice versa. Most hams agreed that the dipole was better even when the "dipole" was actually the G5RV.
> --
> 73, Cecil, w5dxp.com
>

Then I think you'all should just use G5RVs and forget about using tuned dipoles or loop antennas. It just makes more band space for the rest of us when your signals are so far down they are little more than background noise. Best of of luck mates with your G5RVs.

Michael

What some people don't seem to realize is that a G5RV *is* a tuned dipole o=
n 80m, 40m, 20m, and 12m. The twinlead is acting as a series section transf=
ormer to resonate the G5RV antenna system on those four HF bands.

I recently drove 30 miles to a local ham's house to see what was wrong with=
 his G5RV installation. He had it installed as an Inv-V with about 45 degre=
es between the two dipole elements and had the twinlead section taped direc=
tly to the conductive support pole. He had no choke at the twinlead/coax ju=
nction and was trying to drive the G5RV from a solid-state transceiver usin=
g a built-in autotuner. Here are some rules-of-thumb for a G5RV installatio=
n.

1. Make it horizontal at a height of 40+ feet.
2. Keep the twinlead perpendicular to the horizontal dipole and away from a=
ny other conductor.
3. Install a broad-band 1:1 choke at the twinlead/coax junction.
4. Use a good grade of coax, not RG-58.
5. Tune the system with a good broad-range tuner.
6. Recognize that above 14 MHz, the radiation pattern is cloverleaf with no=
t much broadside radiation.

While I am no fan of the G5RV, Cecil does bring up some very important points. They must be installed correctly, just as with any antenna. They do work most all the bands well enough if installed correctly.

I much perfer the Off Center Fed antenna. I do have to give up a few bands with it as it is only about 130 feet long. It does work fine on 80 and 40 meters which is what I mainly put it up for. I do have an 80 meter dipole at right angles to the OCF to compair it to, both at about 50 feet on the ends and no middle support. No mater what the direction, they are often about the same. Sometimes if a station is in just the right spot, one will be much beter than the other. That is just on 80. A triband up at 60 feet is mostly used for 20 meters. Usually it is much beter than the OCF, but even at times the OCF is beter on 20 and 10 meters. Over the years, I have came to the conclusion that almost any antenna compaired to another will be beter in some case, but overall, some are beter than others most of the time.

> I recently drove 30 miles to a local ham's house to see what was wrong with his G5RV installation. He had it installed as an Inv-V with about 45 degrees between the two dipole elements and had the twinlead section taped directly to the conductive support pole. He had no choke at the twinlead/coax junction and was trying to drive the G5RV from a solid-state transceiver using a built-in autotuner. Here are some rules-of-thumb for a G5RV installation.
>
> 1. Make it horizontal at a height of 40+ feet.
> 2. Keep the twinlead perpendicular to the horizontal dipole and away from any other conductor.
> 3. Install a broad-band 1:1 choke at the twinlead/coax junction.
> 4. Use a good grade of coax, not RG-58.
> 5. Tune the system with a good broad-range tuner.
> 6. Recognize that above 14 MHz, the radiation pattern is cloverleaf with not much broadside radiation.

Well written post Cecil.

I don't know antenna theory or the math necessary for the understanding.
I just go on what has worked for me and for my friends.

I have a local mentor here who has very gently moved me from using a 75 meter dipole fed with coax to using a 75 meter loop fed with open wire balanced line.

I live right in town on a 100 X 125 foot lot. I have limited space. I also had a terrible noise level on my receiver. I am surrounded by homes and businesses. He coaxed me into putting up a loop antenna. This is a lot more trouble to do than a dipole. I had to ask a neighbour permission to put a corner of it on his tree on the edge of his property. This reduced my noise level several S units. I was thrilled. I was using 450 ohm window line to feed it. I was also surprised to hear that I was being received stronger in the 200 mile radius of our little 75 meter old men's gang we have. I did not understand why until I read a treatise on horizontal loop antennas.

I felt happy with what I had. Finally after much coaxing by the same mentor, I changed the 450 ohm line to open wire line. The difference in performance was profound. This makes no sense to me and my mentor does not know why this works, he knows from 40 years of experimentation that it does in fact work.

My noise level went down more. Now instead of my S8 meter reading with the dipole, I had achieved an average of an S2 reading on 75. This is my noisiest band. There are often days whey my noise level on 75 is S0. I always have S0 on 20, 15, and 10. I no longer need a tuner for 20, 15, and 10. My worst SWR on these bands is on 20 where it is 1.5:1. I have no idea why this happened. I can use my little ALS-600 and go anywhere on these bands without tuning. I use my AL80B for 75.

I could not understand why a loop reduced background noise so much. My mentor finally explained it to me in language I could understand. He found that I had once experimented with a 2 meter loop for direction finding. He said "remember how deep that signal null was when pointed at the station". I remembered. Well, he said " you are now pointing that loop antenna at all sources of noise coming in from the horizontal plane, namely noise from your town. You only receive signals coming in at an angle." Of course this is also why you lose the noise reduction if you put up your loop vertically.

Once you go loop you never go back :-)

Of course if you live in a rural area with minimal or no sources of local noise there is little incentive to use a loop. My mentor uses a 160 meter 3 element quad mounted with the top at 200 feet. Of course he drives it with open wire. He uses this antenna on all hf bands. He lives in a very rural area on 47 acres. He has spent a lifetime on this property and experimenting with antennas and constructing towers.

Then I think you'all should just use G5RVs and forget about using tuned dipoles or loop antennas. It just makes more band space for the rest of us when your signals are so far down they are little more than background noise. Best of of luck mates with your G5RVs.

Michael

That is not being E D U C A T E D.....

Think about a radio wave as being a real long piece of sausage..

Think about the size of the hog casing it takes to hold one pound of sausage.

You can make the casing real big in diameter, but it will only be one serving and will take a real long time to cook.

Or you can make the casing real long and it will make many portions.

If you only have 4 mouths to feed, and each person only wanted one portion, then making each link 1/4 of 1 lbs would give you the correct amount.

Now if you had 40 mouths to feed and you only have one pound of meat and you make 4 links - each person would only get a portion of a piece...

If your antenna is 20 meters resonant - a dipole being a half wavelength long, then when you have X amount of milliwatts of signal in the air, the tuner looks at it and as long as it can receive it - it will receive it and all is good.

If you take that same antenna and load it up on 80 meters, now it does not have a sufficient portion of the signal, unless the signal is 4 times stronger, for the tuner to receive it and process it and display it as receiveable...

Do you need multiple antenna's to do one thing? NO!

What you do need is one antenna that is resonant everywhere you desire to operate...

The Barker & Williamson BWD 90 does this.
Unless you understand how antenna's works - you will not understand what I am trying to tell you.

If it is resonant everywhere between 160 meters and 10 meters - because it is long enough to receive 160 meters, and everything in between, then it is a good antenna.

Transmitting is only a small portion of the job that the antenna does..
You can receive or transmit something on a wet / salty noodle if it is strong enough, but it is never going to be efficient.

You can use a 100 watt light bulb as a dummy load if you want, and it will resonate some of the power applied, and if the receive antenna is strong enough, the person on the other end, a couple of miles away will hear you.

But as I got into a fight with a educated dummy friend of mine, even though a 100 watt light bulb is a 50 ohm load, it is not a good 50 ohm load, because a light bulb is a non linear resistor.

All he cared was that he could use it as a temporary dummy load and it worked.

This is the same thing you are trying to do with your G5RV analysis.
Just because it works on 20 meters, and everything above 20 meters is a multiple of 20 meters, you think that it should still work.
But unless it is a half wavelength long, or multiples of half wavelength - it will not work.

Because it uses its transmission line as its matching network, you cannot connect a second matching network and match it to another frequency.

Anyone that thinks they can is only kidding themselves...

This is the reason why we call it AMATEUR RADIO, BECAUSE WE CAN EXPERIMENT AND SEE WHAT WE ARE DOING, AND SEE WHAT WORKS AND WHAT DOES NOT!

Even if you get it to work for a little while, sooner or later someone more educated then you is going to come along and tell you that it won't work.
Even when you show them your transceiver and your antenna and all the QSL cards you received - they will tell you not to do it - if they are educated.

When you show them the bill for repairs to your transceiver and your tuner, then they will get the last laugh.
And, when the people on 40 meters, who are doing the same thing you are doing tells you that they cannot hear you and that you must be on a G5RV and laughs at you - then they will get the last laugh!

Then instead of using a more efficient radiator, you will be looking for a amplifier, because you don't understand how your antenna works or what you need to do to make it work, all you understand is more power, which will only get you into more trouble in the long run.

Amplification is only used when all other attempts at using a more efficient radiator has failed.

All signals reduce at the square of the distance away.

The further away you get, the less perceived signal you will have.

If this is not true, then why can't I hear a AM commercial radio station in California at night with 10,000 watts with my $10,000 ham radio when I have a 1000 watt AM station 100 miles away?

Actually, Channel Jumper,

All aspects of your station effect how well it is received. You need to start with a voice that is understandable. This can be a challenge for those hams who are disabled in that way. If you have a clear voice then you need a good microphone to pick up that voice. Then you need a transceiver that will convert that voice into a radio signal without distorting the audio. Then you put that output signal into an amplifier that does not distort the signal. Getting this done is an accomplishment in itself.

You then must have an efficient antenna. The antenna is most often some sort of compromise because most of us do not own acreage. Choosing the most efficient compromise takes some study and often help from another ham.

For those of us who use ham radio for rag chewing, running an amplifier is most often used. There is a good reason for this. Even if you can hear the other station through the static, you are likely missing part of what is transmitted. I am talking about the tone of voice and subtle inflections. Getting up to this level of high quality communications takes a lot of work and expertise.

Everything effects the quality of communications. Care must be taken at each and every stage. If you are using ham radio to talk with a group of friends within a 200 mile radius on 75, you want static free high fidelity sound. This means using a minimum of 1000 watts. This insures that everyone in the group hears everything regardless of their distance to the transmitting station. The square law of radiated electromagnetic radiation makes the use of at least a kilowatt very helpful.

There are those who claim individual elements of the station are the most important. They are most certainly mistaken. EVERYTHING counts.

Michael

The G5RV 102' dipole is 1/2WL on 468/102 = 4.6 MHz.

On 80m, 3/8WL of dipole plus 1/8WL of twinlead = resonance on 80m.
On 40m, 3/4WL of dipole plus 1/4WL of twinlead = resonance on 40m.
On 20m, 3/2WL of dipole plus 1/2WL of twinlead = resonance on 20m.

Actually, Channel Jumper,

All aspects of your station effect how well it is received. You need to start with a voice that is understandable. This can be a challenge for those hams who are disabled in that way. If you have a clear voice then you need a good microphone to pick up that voice. Then you need a transceiver that will convert that voice into a radio signal without distorting the audio. Then you put that output signal into an amplifier that does not distort the signal. Getting this done is an accomplishment in itself.

You then must have an efficient antenna. The antenna is most often some sort of compromise because most of us do not own acreage. Choosing the most efficient compromise takes some study and often help from another ham.

For those of us who use ham radio for rag chewing, running an amplifier is most often used. There is a good reason for this. Even if you can hear the other station through the static, you are likely missing part of what is transmitted. I am talking about the tone of voice and subtle inflections. Getting up to this level of high quality communications takes a lot of work and expertise.

Everything effects the quality of communications. Care must be taken at each and every stage. If you are using ham radio to talk with a group of friends within a 200 mile radius on 75, you want static free high fidelity sound. This means using a minimum of 1000 watts. This insures that everyone in the group hears everything regardless of their distance to the transmitting station. The square law of radiated electromagnetic radiation makes the use of at least a kilowatt very helpful.

There are those who claim individual elements of the station are the most important. They are most certainly mistaken. EVERYTHING counts.

Michael

Yep, I've tried that here at the house. The more bands you add,
the better the chance of some odd multiple working out.
But lately, I've just been using the 80/40. The way I see it, I
can use the 80 legs as a pseudo EDZ of sorts on 30m.
It may be off from a 3/4 WL match, so a tuner is usually required.
But the losses are generally pretty low. As an antenna, the 80m
legs are pretty effective on 30m as far as broadside to the
antenna.
I've always been the same way with 40/15.. I've never added 15m
legs to a parallel set of dipoles. I've always used the 40m legs
for 15m. That goes back all the way to my novice days, when I first
started working 15m. I just used the 40m dipole. My first 15m
novice transmitter was a Viking Valiant. It would match nearly
anything I think.. Tuning 15m using a 40m dipole was no sweat at
all for it.
With my newer sand based rigs, usually need a tuner to keep them
happy. So even when I go up to the dirt patch, I stick a tuner in
the trunk, just in case I decide to take a walk on the wild side.
I've got a couple of smaller MFJ models I can take, and not have to
drag along the larger 989C. But I end up rarely using them..
When I'm up there, I'm on 75m 98.3 % of the time.. I don't get on
in the daytime, as I'm putzing around doing other stuff..
Like mowing grass.. :(

I'm going up there around the end of the month for a few days.
Lots of mowing to do :(, and I've got to rebuild my antenna.. :/

Hi
What happened to those two 989c tuners that was caused by the G5RV because I
have the exact same set up right now. What happened to those dead units? Was
there burn marks or melted fittings or warped coil blades? What would cause
them to fail? There arn't any chips in there, looks pretty solid. And what
if that feed point from the coax at the balun connecting to the 1"
ladderline is only about 10 feet away from the radio? You mentioned 50 feet
but I just can't do that. I am having tough time tuning, I wonder if my 989
has failed.

The usual failure scenario is the wire on the coil heats up,
and it melts the plastic form. Then the wire shifts outward and the
roller doesn't make a good connection.
This is how I got my 989C free.. A friend of mine was doing exactly
what you all describe. He was feeding a G5RV or whatever using that

tuner, and running an 8877 amp.. :|
He melted one coil, and replaced it with another MFJ sent him.
He melted the second one.. He then decided to get a Nye Viking, or
whatever, and gave me the 989C. I then carefully tweaked the coil
wires and adjusted it so the roller would touch, and it's been working
ever since. But I don't use it much.. It collects dust most of the time.

The usual MFJ stuff. Probably ok if you only run it about half what it is
actually rated at.
With the Alpha, he could have been running it over the MFJ ratings.

I have one of the low power MFJ tuners with the switch on the coil instead of the rotary inductor. Bought it new at a hamfest from a dealer. Actually I think I had to get a payment slip from the dealer and walk over to the MFJ booth and pick it up from them. When I got it home, I had to go inside and tigthen up the screws and install one nut that was rolling around inside it. From the few MFJ items I have seen, this seems to be normal.

It seems to tune ok with a 100 watt rig, but the wattmeter is way off compaired to two good meters and dummy load. Set it at 14 mhz and it is ok for 20 meters, but way off on 80 and 10 meters then.

I probably would not have bought the MFJ, but I had just upgraded from Tec to Advanced and did not see anything left in the flemarket. I needed a tuner as the solid state rigs do not like to operate over all of 80 meters as the antenna is not that broad.

Dunno. they are kind of cheap, but I guess they serve the purpose.
And you will often have to derate depending on the load..
Say trying to run a half size dipole.. Easy way to fry one if the
power is high.. I've got one of those little random wire tuners that
I've had since about 1977.. Still use it to this day.. Usually as
my mobile matcher.. I've also got another smaller one that has a
tapped inductor. I forgot the #.. It's out in the garage. But it's a
whole lot smaller than the 989C.. I think it does have a meter in it
as I recall.
Most of the time I'm using a tuner, it's more of as a line flattener
than anything. And that's only on the bands I'm not cut for.

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been
recently revived by an active moderation team.  We are currently seeking
suitable information, FAQ, and bulletin articles from the entire
rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our
newsgroup.

We are seeking a replacement maintainer for the following information
bulletin formerly posted to rec.radio.amateur.* (and currently archived
at http://www.faqs.org/faqs/radio/personal-intro/ ):

 radio/personal-intro
 Subject: Guide to the rec.radio Newsgroups
 Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
 Last Posted: 9 Nov 2001 06:18:17 GMT
 Posting-Frequency: 15th of each month

One significant omission, requiring immediate updates, for this article       |
is that it does not mention newer amateur radio newsgroups created since      |
it was written, including:                                                    |

 rec.radio.amateur.antenna                                                    |
 rec.radio.amateur.boatanchors                                                |
 rec.radio.amateur.dx                                                         |
 rec.radio.amateur.equipment                                                  |
 rec.radio.amateur.homebrew                                                   |
 rec.radio.amateur.moderated                                                  |
 rec.radio.amateur.space                                                      |
```

We are willing to provide any technical support necessary to get this article updated and automatically posted again at a regular interval. This would include establishing contact with the original maintainer for any necessary permissions. We would prefer to seek a new, dedicated maintainer at this time, rather than start auto-posting the original article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to
rec-radio-info-request@panix.com.

Dear Group: I expect to craft a common-mode choke for 50 ohm coax that works from 1.8 to at least 7 MHz using Type 31 (Fair-Rite) core material. Use of any Fe material in coax at the lower HF frequencies is undesired - no center conductors containing steel. Such coax should be able to tolerate being bent with a small radius to facilitate multiple turns through the core - no foam dielectric.

One such coax appears to be the expensive RG-400. Only need a few feet.

Question: What might be a source for short lengths of RG-400? I have tried Newark, Mouser, and the like. . . .

Question: What other small diameter coax uses no steel and has a solid dielectric?

Thanks. 73,   Mac   N8TT

Look here:
http://www.thewireman.com/coaxp.html

They list rg400 at about $ 2 per foot.

They may also have something you need for the choke.

Back when the Michigan State Police used 40 MHz, at some posts static levels would become so high as to reduce range to almost nothing.   Some say it was precipitation noise (as is common with aircraft) and some people believe it had another cause. It seemed to be weather related.

On 6 meters, with an AM circuit I had for years with my father, I have heard discharge noise that starts with a sequence of pops and progresses to a steady roar that occasionally would abruptly stop. (about 100 km path with yagi antennas at both ends)

My guess is it was due to local, enhanced noise. Effects may have been suppressed due to the nature of FM and its mode of squelching.   73,
Mac N8TT

Now the shingles have dried out we can hear each other on all the radios and antennas. I know nothing has changed as the radios need to be programmed by computer and I have the cable.

The distance is just under 10 miles so we should be almost radio line of sight. The land between us is rolling hils. Going from about 600 feet at the lowest to 900 feet at the highest.

Are you looking for low triboelectric noise or low piezoelectric coax?

RG58A/U also known as "Cheapernet". The problem is that I've seen it with both solid copper center conductor, and cheaper copper clad steel center conductor. It also only comes in polyethylene foam dielectric. If it's solid dielectric that you want, you're stuck with Teflon.

For RG58A/U in Teflon, there's Belden 88240:
<http://www.belden.com/techdatas/english/88240.pdf>
which also has a solid copper center conductor.

There's a potential problem with using RG400 or any Teflon dielectric coax in a torroidal balun. It might cold flow. The center conductor might shove its way through the Teflon dielectric and short to the shield braid. I've only seen this in smaller diameter RG188 Teflon coax, but it might happen with RG400. I don't really know if it will be a problem, but methinks you should be aware of the possibility.

** I will look at these sources. Ebay, well, it is Ebay. . .   Thanks.

>Question: What other small diameter coax uses no steel and has a solid
>dielectric?

Are you looking for low triboelectric noise or low piezoelectric coax?
** Fortunately, mechanical forces will be tightly suppressed and thus these
factors are not expected to be an issue. What are expected to be the two
most important factors are a need not to have non-linear effects (no Fe and
attention to avoiding braid issues - you are familiar with the extensive
testing of harmonic production in/with some coax) AND a desire to minimize
the probability of center-conductor migration (staying away from foam)
** A story from long ago: I saw center-conductor migration in RG8 type
(solid dielectric) in a piece of coax that was in a horizontal, outdoor
cable trough. This was a long time ago and it is possible that a
manufacturing defect was involved. Today, one would scan the long piece of
coax and discover such a latent defect if it existed.

RG58A/U also known as "Cheapernet". The problem is that I've seen it
with both solid copper center conductor, and cheaper copper clad steel
center conductor. It also only comes in polyethylene foam dielectric.
If it's solid dielectric that you want, you're stuck with Teflon.
** Thanks. I had just about reached the same conclusion.

For RG58A/U in Teflon, there's Belden 88240:
<http://www.belden.com/techdatas/english/88240.pdf>
which also has a solid copper center conductor.
** I had gone through Belden's info, but must have missed this entry.
Thanks.

There's a potential problem with using RG400 or any Teflon dielectric
coax in a torroidal balun. It might cold flow. The center conductor
might shove its way through the Teflon dielectric and short to the
shield braid. I've only seen this in smaller diameter RG188 Teflon
coax, but it might happen with RG400. I don't really know if it will
be a problem, but methinks you should be aware of the possibility.
** As always with your contributions, this observation is right-on.
Fortunately, volume is not excessively restricted and thus a somewhat larger
radius will be used than the minimum, which should improve the probability.
** Thanks for the help. You are a great source of useful information. 73,
Mac N8TT

Dear Ralph: Thanks! The Wireman certainly looks like a source for relatively short pieces of specialized coax. I have quite a bit of Type 31 on hand that I expect to use. Type 31 seems to be very useful for choking in the lower HF region.

The Wireman must be on my list of suppliers, but too many entries is the bane of the advent of the Internet <grin>.

Thanks again. 73, Mac N8TT

Good, fast, cheap. Pick any two.
eBay is fast and cheap at the expense of good. I buy quite a bit of
stuff on eBay and have had a good success rate. However, about once
or twice a year, I get a lemon. For cheap stuff like coax cable, it's
worth the risk.

PIM (passive intermod):
<http://en.wikipedia.org/wiki/Intermodulation#Passive_Intermodulation_.28PIM.29>
Also watch out for cadmium and nickel plated coaxial connectors.
Heliax and silver plated copper are the best so far. I recently spent
a weekend on a mountain top with a borrowed PIM tester.
<http://www.kaelus.com/Kaelus/media/Site/QR%20Code%20Files/PIM-Testing-Guidelines_Brochure.pdf>
<http://boonton.com/products/pim-testers/pim21>
We had the time to go through almost every coax cable in the building.
According to the tester, with the antennas connected, everything
needed to be replaced. With the dummy load, most everything looked
much better. I eventually determined that we were actually measuring
rectification from nearby antennas and the tower. Banging on the
antennas with a mallet and tightening tower screws fixed that. Most
of the IM came from stainless fasteners on zinc plated tower hardware
which was later replaced.

For an RF polluted radio site, PIM testing is a really good idea.
However, I just don't see it being very useful for ham radio unless
you're doing something that requires full duplex operation.

>** A story from long ago: I saw center-conductor migration in RG8 type
>(solid dielectric) in a piece of coax that was in a horizontal, outdoor
>cable trough. This was a long time ago and it is possible that a
>manufacturing defect was involved. Today, one would scan the long piece of
>coax and discover such a latent defect if it existed.

I still use a home made TDR (time domain reflectometer) for testing
cables. Old habits and methods die slowly.

I usually have the opposite problem with coaxial cable. For example, I would solder connectors onto a 100ft roll of RG8/u while it was still rolled tight on the spool. Bad idea. When straightened, the center conductor becomes slightly longer than the shield. The stiff center conductor tries to push the center pins out from the connectors. In one case, I found a mangled N connector pair where the center pin had shoved its way into the mating receptacle.

I've seen what I suspected was center conductor migration on long horizontal coax runs, but have never done a post mortem on the coax. By the time it gets to the point where it's shorted, other problems (i.e. losses) usually inspire a pre-emptive replacement. These days, I just happen to have a roll of RG6/u with a messenger wire attached, which eliminates all the stresses.

Good luck, whatever you're building.

Do you have any construction information available for your TDR?

Ooooo, thanks for the heads-up. Great comment!

John

That noise sequence is exactly what I hear when I see a corn snow squall come through my property in the winter. I have actually watched the wind blown snow come closer and closer while the HF radio noise increases until all signals are wiped out, then when the back edge of the squall passes the antenna, all is quiet, again.

I live at 2800 ft in the Central Oregon desert. The antenna is either a ground mounted 5BTV with 40 radials, or a 160 meter horizontal loop at 35 ft.

A long wire from outside that goes directly to the receiver's asymmetrical input will very likely provide sufficient signal for the receiver. It may also receive lots of noise from indoor electronic/electrical equipment. When external noise dominates, further wire length increase will not help (excluding the very loooong ones that operate in traveling wave mode).

If you have the possibility, use coaxial cable for the interior part (75 or 50 Ohms). Don�t worry about mismatch, for reception you just need sufficient signal.

Make sure you connect the braid of the exterior side of the coaxial cable to a ground provision. This can be a ground stake, but every large metallic structure can be used for that. You may add some common mode choke (based on ferrite cores or rods) to further reduce the effect of indoor generated noise.

If you live in a very low noise environment, using a 9:1 transformer will give more signal and noise, given certain wire length. If external noise already dominates, spending lots of money for a 9:1 transformer will not increase your S/N ratio.

Regarding the long wire or loop discussion; whether a loop is useful or not depends on frequency band and local EM environment. You need to try as you can't say beforehand what will work better.

For the cost of the B&W BWD 90 you can get a tuner and use a more simple dipole. The B&W is really just a big dummy load of an antenna. I have worked several stations that use them and they were not very strong compaired to other stations near them. The military uses them because they can run plenty of power to make up for the short commings of the B&W. Also they operate over many frequencies and want something simple that will cover them. It is almost like a radiating dummy load.

The G5RV is ok if high enough. Still nothing special except for maybe 20 meters if the stations are in the correct direction. It does need tuner for transmitting.

For just receiving, just about anything is ok as many have mentioned.

There is nothing wrong with the Icom 706 for casual use. I have one and a 746pro and they compair very well for casual usage except for the filtering the 746 has. I do have a cw filter in the 706 that helps out for cw and rtty. For the price, the 706 is a fine radio.

A very nice antenna is the horizontal loop. If you feed it with a open ladder line you can work the whole HF band. At the station side you need to use a balun, the guanella balun does a great job.

You don't even have to make the loop resonant, I have a loop with 135 meters circumference, the feeder is an open ladder line ending in a guanella balun. I can use all bands from 160m to 10m on that antenna, using my rigs internal match.

No matter what antenna you finally choose, you have to get it up as high as you can, if you want to get connections from far away anyway.

I think it is more then obvious that you do not know what you are
talking about when it comes to antenna's.

The key to any antenna is LOCATION / LOCATION / LOCATION....

If you are in a crappy location, it is not going to work well...

If you are in a good location, the B & W 90 will out talk your Carolina
Windom or any other long wire antenna, due to the fact that antenna
tuners reduce the amount of power applied and they do not physically
tune the antenna, just the coax to the antenna. The only tuners that
works is the ones that are placed directly at the feed point of the
antenna, not something inside of the shack...

The B&W 90 on 20 meters acts kind of like a beam antenna, which exhibits some forward gain - due to the nature of it's construction.
The one wire acts like a reflector while the other wire acts like a driven element.

On 40 meters it still acts like a 1.5 wave antenna and on 80 meters it acts like a Dipole antenna...

On 160 meters - if you wanted to be all that you could be - it would need to be 80' or more } depending upon terrain } off the ground to get in the right place for it to be at optimum height...
It also depends upon the ground {earth } underneath the antenna...
Wet / swampy earth is always better then rocky dry soil....

You have to realize what arrival angle the DX signals come in at and the fact that there is two signals you are receiving, both the direct path { good} and the reflection off the earth { bad} at Gb before reaching our station location..

Unless you compared the two antenna's at the same location at the same time, at the same height within one hour of each other, there is no way for sure for you to comment about which antenna works best...

10 - 40 meters band equals about 19.9 meters of height mininum / needed to get optimal angle.

20 meters likes about 32 meters of height, heights between 15 and 32 meters - { 50 - 105 feet are about as good as you can get} for anything between 6 meters and 160 meters....

Most people just puts their wire antenna in a tree about 40' high or strings it up between two towers and calls it good enough.
The problem is - there is a null on the ends of the antenna and the path that the signal uses isn't always a straight line...

The problem is - with a 160 meter antenna, this is hard to accomplish, hence it is easier to use a vertical antenna for 80 and 160 meters - but is very expensive to use a base tuner and a 80 / 160 meter vertical antenna - which must be supported by some type of tower in most locations.

The wind would damage it quickly and its survival rate would be poor without some type of support...

At the same time, my antenna is mounted 20' off the ground between two houses, and a jib boom mounted on the back of my house, fed with 40' of cheap Radio Shack coax and it still talks well in most directions.

I can hear north / south / east / west with a antenna that is aimed east and west and sometimes when the Maritime Mobile net or the YL network needs a relay station, I can relay between two signals - where they are using some type of beam antenna for the monitoring station and the person trying to check in either has a beam with a poor signal or a

G5RV...
And I never run more then 100 watts!

Even when they are running 1000 watts - my signal still is better then
most peoples signals on 20 and 40 meters....
If I really need some help, I just turn on the processor and it has
enough compression that I can get through, even when there is a pile
up...

From someone that did not know about the ringo type antenna and what it took to make it a halfwave, you make the statement that I don't know what I am talking about when it comes to antennas.

Now you are saying that because the B&W has two wires it acts like a beam. This is not correct at all.

A tuner will allow antennas to match the nominal 50 ohm output of a transmitter to the antenna system that is not 50 ohms. You will loose about 5 to 10 percent of the power in a tuner. That crappy B&W burns up most of its power in that big resistor in the middle of it.

The simple wire antennas while having gain in one direction will not have gain in another direction. Unless you have specific stations to talk with, the gain may be useless if it is in the wrong direction.

Talking about pot=kettle=black... :/

>
> The key to any antenna is LOCATION / LOCATION / LOCATION....

I don't think the guy is going to move so he can have the
optimum location to string up a wire..

>
> If you are in a crappy location, it is not going to work well...

That would generally apply to any antenna installed in that
location. But for what he wants to do, which is merely listen
to the HF bands, almost anything is going to do reasonably well.
One poster had a point about possible shack noise, but not all
homes are huge noise sources. I remember as a SWL, I often ran
simple random wires, merely stuck in the center conductor, and
had perfectly acceptable results. If shack noise rears it's ugly

head, then it's time to consider other options.
But it's quite possible that shack noise will not be a huge issue.
You never know until you try it.

That's silly.. Do you think that matching at the feed point
ensures no loss? Better think again..
It would be quite possible for a shack tuned system to show
less loss than the B&W, if designed right, and one used the
very least inductance needed to get an acceptable match.

It most certainly does not.. It acts like an appx 3 wave long folded
dipole..

>
> On 40 meters it still acts like a 1.5 wave antenna and on 80 meters it
> acts like a Dipole antenna...

Well, almost.. It's a bit short on 80, and with the resister at the
feed point to match it, it would never be as good as the full size coax
fed dipoles I run. Ever.
Mine require no matching whatsoever. Zero, nada, zip..

Even 80 feet is fairly low for a 160m dipole, but this is not a strong
issue being as he only wants to receive.

How are you going to receive a space or ground wave from a DX station?

>
> Unless you compared the two antenna's at the same location at the same

Can't really argue with that.. But it is fairly easy to predict..

>
> 10 - 40 meters band equals about 19.9 meters of height mininum / needed
> to get optimal angle.

But what is the optimum angle? It's going to vary, depending on the
path. And each band would need a different height to be optimum at a
certain angle. It's not worth worrying about in his case, unless he
wants to chase his tail.

>
> 20 meters likes about 32 meters of height, heights between 15 and 32

Sure.. Almost anything is going to work at 96 feet in the air..
But it's overkill for what he wants to do, which is merely receive.

This is going to be the case no matter how high it is. I bet the
nulls would actually be more pronounced the higher you installed it.
Not that it's something worth worrying about for general receive use..
He's still going to receive signals in the null directions. They just
might be down a tad vs the favored directions.
The pattern off a dipole that long would likely be like an "X".

>

Huh?? Why would base feeding a 160m vertical be expensive?
It's never cost me much money.. :/

A random length of wire strung around your yard, and coming to the
central connector of your coax plug, will probably give you more
stations than you know what to do with.

If you want to get fancier, MFJ makes an inexpensive random wire tuner
(#16010) that you can peak for maximum signal strength. This is
something you could also use when you get your license and are ready
to transmit.

You could also build a random length dipole, and feed it with coax,
connecting the center conductor to one leg, and the braid to the other
leg.

Lots of options here. Start simple.

I want to build a home made omni for use on tower.

I want to feed it with coax and have lot of wire, copper pipe, tubing, basic parts.

I have a pretty good tuner and will use the tuner to tune. Can anyone make a recommendation as to how to make a not so complicated omni directional antenna that practical?

I am thinking something about 6 to 10 foot in height only, I can make gnd planes, but something I can tune to get most bands and simply omni function. I want to get all bands and I run barefoot and just want to get on the air with simplest, least complicated, easiest to build omni. I don't need a electronics lesson in engineering design, just a website or two explaining the simple build of the magical omni fed with coax that is the best I can get for my situation.

Thanks

73s

I thought of that but there are a bunch of other things on there like TV antennas, dishes, clothes lines, back yard lights, etc etc. Stunt it, just wanted to throw up a crazy idea, I know it is a very broad question. What is the smallest thing I could use with a pretty good tuner? On top the utility tower?

How about a car/truck "screwdriver" antenna?

>>> I have a pretty good tuner and will use the tuner to tune.

The combination of a short vertical, a tuner in the shack, and a coax feed, is not a particularly happy one.

You *may* be able to tune it, in the sense of presenting a load to your transceiver which won't cause its output section to complain or leak blue smoke. However, the losses in the tuner, and (particularly) in the coax feedline, are likely to be very high... you won't get much signal out, and you may end up with high enough voltages on some sections of your coaxial feedline to cause arcing (even at "barefoot" power levels!)

So, the two approaches I can think of which might work would be:

(1) A "screwdriver" antenna or equivalent... a vertical whip (longer is better) and a remotely-adjustable loading coil.

(2) A vertical whip, and a remote-controlled (or self-controlled) antenna tuner / transmatch mounted right at the base of the whip.

In either case, you'll probably need to use the tower itself as the "ground" (counterpoise) for the tuned antenna... plan on running some heavy, low-impedance braid from the tuner to the antenna mount point.

You have set yourself up for quite a challenge! Limiting yourself to a length of "6 to 10 feet" is going to be a problem. At ten feet you'll be more-or-less resonant on 10 and 12 meters, and will be able to use the tuner for 15m and (maybe) 20.

Even much longer antennas don't work all bands, although some use coils to improve coverage.

In short, a shorty antenna will not work well on all bands. If you have room, you'd be better off with separate verticals for each of the bands you want to use.

I thought of that but there are a bunch of other things on there like TV
antennas, dishes, clothes lines, back yard lights, etc etc. Stunt it, just
wanted to throw up a crazy idea, I know it is a very broad question. What
is
# the smallest thing I could use with a pretty good tuner? On top the
utility
# tower?

With an antenna that short, you will need a ground for it to work against. If you can manage that with guy wires etc., let me relate my recent experience.

I use a vertical mounted above a metal patio cover, which is about 15x30 feet, roughly 10 feet off the ground. The feedline is 15 feet of RG8 to a tuner.

Initially, I installed a 9 foot CB whip antenna. It worked quite well on 12 and 10 meters. 17 and 15 meters were hard to match, and marginal contacts were made on 20 meters.

I replaced that whip with a 14 foot whip. It worked quite well on 20 meters through 10 meters. I was quite happy with it, but got the bug to experiment some more.

lastly, I replaced the whip with a 17 foot whip. It works well on 30 meters through 15 meters, and can be brute force loaded on 40 meters through 10 meters. I don't have much performance info, since the bands have been stinko for a while.

Both the 9 foot whip and the 14 foot whip did a credible job during the last set of DX contests, with the 14 foot clearly being better.

In summary, if the antenna is 8-10 feet, I wouldn't count on getting much performance other than on the higher bands, say 15-10.

Have you chosen a frequency you might want to use? That's kind of
important.

:) I was wondering the same thing. There's a lot of difference between antennas
for 4 MHz and 440 MHz.

Hi
Thanks for all the info and advice and ideas.

I have the 102 foot dipole up there now, my problem is I just put a TV antenna HD (two 8 bay bow tie Channelmaster) antennas right above the dipole's center point (about 1 meter away) and now I am having difficulty tuning that dipole for anyband. In fact if I try too long the old 1970 transceiver shuts off automatically and scares me that I may have some of that blue smoke you talked about. So I wanted to get something above it, omni that would work as well as the dipole did work. Something simple, and easy becuase nothing up there on the top now.

I think as you folks mentioned the omni fed with coax at short lengths will be difficult unless it is long enough and with gnd planes, but first wind storm will bring it down.

I will focus back onto the dipole. Do you think it is too close to the new TV antennas? Would that cause the innability to tune it where I was able to before through the manual tuner?

What would be a suitable distance from the center point of that dipole to be away from anything that would cause such innability to tune. Right now I am thinking one of the legs of the dipole are fractured and that is the problem. I don't have a way to test each leg of the dipole, it is about 50 feet of ladder line and then each leg but how do you test from the shack if there is a fracture without the fancy scopes that you guys have? Other than bringing each leg down and using ohm meter from one end to the other.

Any comments about having those channel master HD antennas too close to the center feed point of a dipole? And the havok it can do to an old transceiver and tuner?

Thanks

73s

I doubt the TV antenna is affecting the dipole. You may have broken the dipole or feed line when you put up the TV antenna.

Also check to see that you did not put the TV feedline too close to the dipole feedline.   It should be atleast a foot or more from it..

I think you are right in your statement of breaking the dipole or feedline upon installing the tv antenna.

The tv antenna feedline is no where near the ladder line, about 4 feet distance.

I suppose my next move is to pull down the dipole, check, and either fix or eliminate that as my problem. I was hoping I didn't have to do that. But if that copper solid wire, both in ladder line and dipole had fractured, I would think it would be visible from gnd (about 35 feet height). All worked before the tv antenna installation, and yes there was a lot of banging and jamming and bumping of that dipole while installing the TV antenna but nothing is visuably broken, maybe a hairline fracture. Looks like a climb is in order. That is not one of my most favorite things, climbing 50 feet above the ground on a self supporting tower. I hate climbing but do it every time. I will let you know how I make out, probably climb today or tomorrow, looks like rain.

Thanks and 73s

While you are up there you may want to extend a pieceof pipe off the tower
and put a pulely on it. Then put a loop of small rope that goes to the
pulley and back to the ground. That way you will not have to climb the
tower as often.

That is great idea. I have a piece of plastic pipe extending out about 6 ft from the tower, about 45ft from the gnd, it is 2" ABS plastic pipe with a hole in the end so just need to run the cord through there without the pulley idea. I ran the ladder line straight up, the pipe holds the entire weight of the dipole, ladder line which I spun a few times for wind resistence. I have always had luck with that dipole, and really wondering why it failed. It shouldn't have as it is only about 2 years old. I must have damaged it when doing other things. That is my goal today to bring that down and find the damage and repair it.

Now here is my querry ,,, I have a omni antenna I purchased at ham fest years ago. I had it up on the tower for SWL for longest time and worked well and also worked well when in transmit.

i used the big tunner to keep what I thought was safe levels of returned power. I want to put this back up and use with big tuner and 1970 transceiver.

http://www.intelgold.com/vk4uq/manuals/Hidaka%20VS41-VS80KR%20-%203.pdf http://www.intelgold.com/vk4uq/manuals/Hidaka%20VS41-VS80KR%20-%202.pdf

Now I can fabricate some aluminum gnd planes to go with this, this should be
on the ground but I want it in the air. While the traps and entire antenna
looks good shape, how can I tell if those traps are in working shape before
spending all the time cleaning it up, erecting it, etc etc, only to find it
is dead? The traps are completely sealed in there, the antenna looks about
as old as the transceiver, if not older. I am on a shoe string budget of
course so I cannot buy one of those fancy all band omni antennas, I have to
build.

Please comment on this antenna and my ideas about getting it working 50 feet
above the gnd.

Thanks

73s

To check the vertical without any special equipment, you may have to install it at ground level and see how the SWR is.

I do not think I would try to put it on the tower. If you look at the instructions, you will need atleast 3 or more radials for each band and some of them will be about 60 to 130 feet long.

I was thinking of 4 radials about 8ft length.

Now I think because of height and present elevation and the big tuner it will function safely, what would be the reasons why not to use this? I am sure there are loses at the tuner, loses at the coax, loses becuase of poor gnd planes lengths and numbers, but there has to be some gains. It works would be a big gain.

Would there be mass interferrence on anything?

I (and probably many others) have a wireless router in the house which in
my case runs at 2.4Ghz via a single antenna about 10 cm high. Certainly
omnidirectional which is my issue. As its against a wall near the road 1/2
the signal
keeps neighbours and passing traffic with a WiFi point. Or at least is just
wasting 1/2 the radiated power.
   My questions are : Is putting a reflector adjacent to the antenna on the
road side sufficient to screen off the signal? A follow on from that is
would that reflected signal boost signal levels in the house?.
  If the info provided is not detailed enough, sorry about that. Question is
born of ignorance which is rectifiable!

Many thanks
John

Hi John.

If you're using the router's security (password, unique ID etc) then it
shouldn't be open to neighbours and passing traffic.
A reflector will not reduce that power wastage you mentioned.
Is the router in the best place for your use in your house?

Best wishes, Ian.

I have a different opinion than Ian.
Installing a reflector will weaken the signal going towards the road and
enhance the signal in the other direction.

Here's an easy one to build.

http://www.freeantennas.com/projects/Ez-10/

and another

http://www.freeantennas.com/projects/template2/index.html

If you put some aluminum kitchen foil at around 0.25 lambda (1.2", 30 mm behind antenna, about 1 square foot in size) behind the antenna, you will reduce the radiation to that direction and icrease the radiation perpendicular to the aluminum kitchen foil. The radiation pattern will be close to that of a single resonator patch antenna.

You will not screen it completely as due to multiple reflection it may/will reach the road again, but it may improve indoor coverage.

There's always some location where your wireless router is going to be heard. You can reduce the signal by placing something either RF absorbent or RF reflective between the antenna and the road, but you'll never get rid of all of the signal. Someone with a high gain (dish) antenna, can probably pickup enough signal if they are sufficiently determined.

Your best protection is the encryption built into your wireless router. WPA2-PSK-AES is the best.

As for improving the signal in other parts of the house, that depends on the shape and composition of the house. 2.4Ghz does not penetrate walls very well. If the walls are hollow and mostly wood, they're almost transparent to RF. However, if the walls are stuffed with aluminum foil backed fiberglass insulation, very little will pass.

Optimizing the antenna pattern to best cover the house is possible, but there are limitations. Antennas do not create RF. The merely redirect it. If you want to increase the amount of RF in one area, you have to do it at the expense of other areas. For example, since your omnidirectional antenna wastes some RF aimed toward the road, a simple reflector will bounce much of this RF back into the house. That may help or hinder depending on whether the incident and reflected signals add or cancel. For a start, a large sheet of aluminum foil taped to the wall might be useful.

I use an Android phone app called Wifi Analyzer. Among other features
it has a pseudo analog type meter showing your WiFi signal strength
that updates every few seconds so it will give you an idea of your
antenna pattern as you walk around your house.

Also the app can tell you what WiFi channels your neighbors are using.
If possible set your channel as far away as possible from the
strongest signal (likely your next door neighbor) and it may increase
your speed.

Gents(?)

Many thanks for replies. As you say Security may be provided other ways . In some ways my wife and I are Luddites and our phone can do phone calls and thats it so Aarons suggestion is out. My laptop though has a six segment "bargraph" for router signal strength. I,ll follow yours suggestions and see what happens. I,ll nick some of good wifes Alfoil.

John

I think that someone here is over stressing the thought process of how their wireless system works.

NO your antenna is not OMNI Directional - that is called a ISOTROPIC, and a isotropic antenna is a mythical antenna - rumor is a paper clip on 160 meters - 1.8 MHz is a true Isotropic antenna.

A vertical antenna has lobes the same as all other antenna's.

There isn't any way to reflect your signal - all in one direction to improve service in one direction and block service in others - other then the modification and use of a sat dish, and even then, that is just for point to point communications - Line Of Sight.

A NANO station on the roof would allow your signal to be received up to 18 miles away - Line Of Sight..
Anything made by man can be listened to by man...

A wireless Modem is very primative technology - but beyond the reach of most people walking the street.

The purpose of the name and password is not to keep people out of your system - spying on you - you ninny.
But to keep unauthorized people from using your system...

You see - the cable company or service provider gets PAID for each of their customers.
When you open up your link - someone gets to use your WIFI for FREE!

The cable company or service provider is LOOSING MONEY.
They don't want you to give away their service for FREE...

No one without some type of college / technicial school degree, and a lot of expensive equipment, can hack into your personal computer no matter if they have access to your internet or not.

All you are doing is wasting your time and ours with this question - it is silly to worry about something like this, unless you are doing something illegal and are trying not to get caught.

I built a house for a man 30 years ago, in which we covered the entire house with a heavy gauge aluminum foil , roof / walls, floors, windows / doors and grounded all the aluminum to earth ground.

I discovered that the nails used to penetrate the aluminum foil, to hold the shingles on the roof and the siding on the walls radiated the RF signals better then if he would have just left it bare - no shielding at all.

NOW - if he would have used a copper based foil, and used copper nails - he probably would have accomplished what he was trying to do.

The walls on this house were 12 inches thick and insulated with spray foam - new technology at that time, and he used a air exchanger because the house was so tight, it would actually accumulate moisture inside of the house from your breath.   You could heat the house with a 100 watt light bulb or a candle in each room.

Needless to say - he lived there for 30 years, applied for his social security at the age of 62 and promptly died before he received his first check...
All of the money he saved in heating bills, paid for the insulation and the aluminum foil. The roof did have to be replaced one time in 30 years.

The house now sits idle, because no one knows what to do with it.
I doubt if you could hear his WIFI signal from outside the house, but why bother?

Get rid of your antenna, run wire to each room and connect directly to the internet and don't worry about it.

Just keep one thing in mind.
When Joe Paterno was arrested for a crime he did not commit, his email records were retreived for the past 12 years.
So everything you do, everything you say is all being digitally recorded and stored someplace.   So your very best bet is not to say anything you do not want others to know about. Not to visit any site - you do not want to be held accountable for, and not to text anything over your cell phone.

ps - even the digital cell phones can be listened to - if you have the right equipment. If the cell phone companies has the technology - definately the people who makes that technology also has receivers.

The State Police, FBI , CIA and a whole list of agencies doesn't even have to use a antenna to receive it. They can access the towers via the internet and listen to your cell phone calls in real time and can even record them for future reference.

So nothing electronic is secure!

Me personally - if I want to use your wireless internet connection, I

will hack into it, and you won't even know that I am doing it.
Its much easier to have the equipment to take it directly off the coax
of the Comcast then it is to receive it via OTA, and the signal is more
reliable and quieter and faster.

Basically your signal is receiveable for a distance of about 150'
How long can a car traveling past your house use your WIFI connection if
it is traveling 35 MPH?
How far away are your neighbors?

Get all of them to give you $5.00 a month and give them the password.
10 or 12 people - and it would pay your internet bill for the month..
Quit being so stingy...

```

I live in a quiet rural area of North Carolina. I leave my wireless
connection open in case my neighbors or folks passing through can use
it if they have a need. It is also open at my church and my fire

```
station. No vandalism so far. Several parents who used to drop their
kids off for programs now find a quiet classroom and hang around. A
couple have owned up to stopping by in the daytime for a quiet place
to get some work done. It is a plus that cell phones don't work there.
As far as the Fire Station goes, we are 100% volunteers and anything I
can do to encourage the firefighters to hang around is simply good
business.
Of course, your world my be a lot different than mine...

Not overstressing thought process at all CJ and was aware of all, repeat all, your comments. Previously in
first post I was quite open in stating my 50 years experience in electronics was at opposite end of spectrum. Principally in medical electronics design where typically heart signals dont hold much info above 1kHz.

End results of this particular issue though is great success. I think I used all suggestions put forward to some extent!!. Resited Router from behind Monitor to avoid shadowing from metal chassis. "She who must be obeyed" didnt think much of a reflector as described as decoration BUT I noticed the router was in front of a picture about the same dimensions/distance as suggested for a reflector. Covered the picture back in foil.

Bargraph is now sitting on all segments!!!. Many thanks again everyone, education is a great thing..

I lectured in Digital/analogue for many years and found ignorance is not the same as stupidity but the reciprocal almost always hold true.

John

```

Building a G5RV which will be 102 ft and fed with 450 ohm ladder line and will be about 40 ft above the gnd.

Because the hole in the wall next to my shack has several coaxes, a gnd wire (coated) going through the same pipe (1-1/4") pvc. from shack to outside to tower then up. About 7 feet from back of tuner through wall then upward sweep towards center of dipole (about 35 feet).

Should I use a 50 ohm coax through that hole, to the tuner (no balun) then to the ladder line? Or should I simply run the ladder line through that hole, beside the other wires (touching) but both have insulated jacket or pvc jacket. But very close through that pipe. The ladder line connects to the same tuner (balun).

I am worried about running the ladder line feed through that hole beside all the two other coaxes, and a gnd wire. They have to go through the same hole pipe. Which is better, only running lower power (less than 100 watts)?

Thanks

73s

What some hams do is switch from ladder-line to short parallel runs of coax
through the wall. Tie the ladder-line conductors to the center conductors on the
two pieces of coax and ground the outside braids. The balun can be located on the
inside wall.

While the ladderline is insulated, the RF extends for a distance from the ladder line. It should be several inches or more from anything that is conductive.

That said, use coax from the shack to the ladder line of the g5rv.
The ladder line does not usaully go to a 4:1 balun, but a choke 1:1 type of balun then to a 50 ohm coax.

I have a balun in the tuner for the ladder line but not for the 50 ohm coax.
Should the 1:1 balun be right at the bottom of the ladder line? Or can it go
without a balun?

You can feed the ladder line with 50 ohm coax. That is the way the g5rv is designed. It is sometimes helpful if you put one of the choke type baluns at this point. That is the kind of balun that is a piece of coax with the ferrite beads over the outer portion of the coax.
This will help keep the RF out of the shack if it becomes a problem.

The g5rv does not need a 4:1 type of balun at the feed point of the ladder line as it is designed to be near 50 ohms at that point. That is the reason the ladder line needs to be the designed length. Then you just use 50 ohm coax to go to the tuner. Shorter or longer and there will be problems.

YOu can make the 50 ohm coax any length you need.
The critica length is the ladder line. It must be the design length for the
g5rv. This line is what converts the impedance of the antenna to near 50
ohms.

This answer is correct, however - it seems that you do not know what you
are doing, especially since you chose to build a G5RV antenna.
A G5RV antenna is only resonant on 20 meter ONLY - PERIOD!

Using a tuner with a G5RV does not improve its performance anywhere else.

I have two MFJ 949's - Both Broke, both were broke when I bought them.
I believe both were ruined when they were connected to a G5RV and were
operated on 10 or 40 meters.

The ladder line is the matching network.
This is what made it resonant on 20 meters ONLY

After the ladder line - you add the Balun so you can bring it into the shack.

The purpose of the ladder line is so you hang it 40' or more above ground.

And - the ladder line needs to be at a 90* angle from the dipole for it to work.

So there is no extra ladder line left over after you put it up.

You want the feed point of the antenna 50' away from the shack.

The RF it emits is so bad - your computer and mouse will probably crash if you used it with any type of amplification and was too close to the computer..

The only purpose of building the G5RV is maybe to experiment with non resonant antenna's or to try and save a couple of dollars - if you already had the materials to make one.. Since the cost of a professionally built G5RV at most hamfests is about $65.00

The man who designed and built the G5RV - Varney - went nuts from trying to make this antenna work.
If he was alive today, he would tell you that he was sorry that he ever designed it and that it did not work very well anywhere...

Your money would be better spent building a double bazooka which would be resonant with a antenna tuner on more then just one band!

If you would like to purchase a G5RV - I have a brand new one here - still in the bag, used for two weeks and rolled back up again..
AND - I am not made of money, so if it worked, you can bet it would still be up yet!

$65.00 delivered to your front door!

That looks like next antenna, I am already committed with the materials I have. I have lots of solid copper wire 16ga and 450 ohm ladder line. And I don't have enough coax, only about 10ft left. So was gonna plug it together without running to town. I seldom return early when heading into town.

Yes, the original G5RV was originally intended to be a 20M only
antenna. However it was soon found that a 102 foot version used with a
tuner, some times without ladder line, at elevations near the ground
to way up there could be use full on other bands. All sorts of
matching schemes have been used and a tuner at the radio end helps
clean things up. A motivated Ham can get reasonable results most of
the time.

10 Meters is a little tricky for the 102 foot length.

If you have a tuner that was damaged trying to tune a G5RV the only
possible explanation is that of a misinformed or careless operator.

"you do not know what you are doing" Is disparaging troll talk.

The G5RV can usually be a pretty good all-purpose HF antenna - subject
to certain limitations - and even some of these have been got around
with various modifications etc. It's worth doing a Google on
'G5RV+original'. In particular, this paper by L B Cebick contains a lot
of good information.

It doesn't matter if an antenna is resonant or non-resonant. What matters i=
s achieving a conjugate match somewhere in a low-loss antenna system. The G=
5RV achieves a relatively low-loss conjugate match on 80m, 40m, 20m, and 12=
m using a tuner. Here's a quote from G5RV himself in 1984 from the ARRL Ant=
enna Compendium, Vol 1:

"The G5RV antenna, with its special feeder arrangement, is a multiband cent=
er-fed antenna capable of efficient operation on all HF bands ..." I person=
ally don't agree that the G5RV is capable of efficient operation on 30m, 17=
m, 15m, and 10m.

When the G5RV was first conceived (1946), we didn't have 30m and 17m
(introduced early 80s) - nor did we have 15m (1947). Maybe he was just
being a bit optimistic?

In Mr. Varney's 1980's article, he recommended a choke, about 8-10 turns of coax in a coil about 6" in diameter, taped together, with the coil right below where the coax connects to the ladderline. (The coil and the coax feed are both of one piece.) The coil can keep rf from flowing on the outside of your coax.

He is also mislabeling the names of the various antennas, and
makes it hard to tell what the heck he really has..
A Ringo Ranger is a VHF or UHF antenna, and is a twin element
collinear vertical. It has a phasing stub type deal between the
two elements. The 2 meter version happens to be about 8.75 ft tall.

A Ringo is a single element halfwave vertical. And Cushcraft does/did
make a 10m version. It's the AR-10, and is appx 16 feet tall.
So I'm starting to wonder if they are using a 2 meter antenna for
10 meters.. ??
It would be fairly easy to convert the RR to a 10m ringo..
Extend to 16 feet, and you would need to use a larger gamma loop,
and a bit longer piece of coax for the capacitor.
I've made them before, and used 1/4 inch copper tubing to make the
gamma loop.
BTW, a 10 meter ringo does not require radials. But it can be
further improved by adding a decoupling section a 1/4 wave down
from the feed point. I used a union to ground the shield to the
metal mast at that point, and had three 1/4 wave radials.

The big selling point when they first came out was no radials needed. I am not sure as it has been a long time ago, but was thinking the origional Ringo was for the CB because of no radials and later moved to other bands.

Then it was found that on the vhf bands the signal went up instead of out to the horizon. That is when the extra piece of coax was added about 1/4 wavelength below the antenna and radials added.

From all I have seen, the Ringo was one of the beter selling antennas and it did not work very well. Same as for the 11 element beams that CC made. Several items like that turned me off from CC years ago.

Tom, here's what John said: "For instance on a full length dipole the ceter=
 feed would be at max amps and lowest volts.etc.I can get this far but how =
the wire becomes capacative or inductive along its length i cant figure."

I assumed that if he already understand "max amps and lowest volts" and cou=

ld "get this far", that he already understood the in-phase addition necessa=
ry for "max amps" and the out-of-phase (subtraction) necessary for "lowest =
volts". That's why I said, "You say you understand why the resonant feedpoi=
nt is resistive so - so far so good?"

My dictionary does not give "easy" as a definition of "basic". It says "bas=
ic" means "fundamental". I don't know how to get any more fundamental than =
to discuss wave action at the individual component wave level.

An ordinary wire dipole strung vertically will give better SWR's than you got. It can be tweaked to give 1.5: 1 worst case across the band. When I find the dimensions I'll post them.

```

Thanks guys - I found the answer this morning as soon as I looked at the picture of one on the web site...

The seller of the antenna was dead - I couldn't ask him any questions.

His son - was only interested in the money from the sale and couldn't tell me anything because he wasn't a ham like his dad.

The antenna was a 6 meter antenna - hence this antenna would need to be about 224 inches long to work on 10 meters - not 9'

How ever - 138 inches divided by two would be 69 inches which would show some kind of match - but not the one desired.

5'9 x 2 = 11'6 which did show a match with a 2:1 SWR

This means I need to add another 7' to the antenna to get it to work on 27.200 MHz...

All I would need to do is figure out how long to make the stub match and I would be set!

For some reason a 6 meter antenna will receive on 10 meters - ok and will tune up on 10 meters if it is the right length and if a antenna tuner is used.

For some reason the 6 meter Ringo - if not properly adjusted will not transmit on 6 meters - it is a 1 MHz only antenna - not very broad banded...

When I tried it at my house on 50.125 MHz and 52.900 Mhz - it would not tune with my internal tuner in my Kenwood TS 590 - said bad match...

But it would tune just fine on 10 meters - 28.400 - so I figured it was a 10 meter antenna... I didn't get the instructions with the antenna - and I didn't look online to see which model it was.... That was my fault...

Makes a real good dummy load though...

Thanks guys..

--

About 16.5-17 inches long with coax that has a .66 VF.
It's not too critical.
I'm not sure if the 6m ringo has a large enough gamma loop..
Maybe, if you used most of it.. If it won't match, you could
make a larger loop from copper tubing.
I make the loops from the tubing, then I hammer down the ends
of the tubing so they are flat, and then drill the holes in
the flat part so it can be attached to the mounting hardware.
With a little tweaking of the tap location, you should be able
to get a near perfect match. Don't bother trying to trim the
coax cap.. It's not that critical.. For most 10m half waves,
appx 50 pf is the usual value used. And that cap is actually
optional.. Note that the 6m version did not use a coax cap.
But I've always used one on the 10m ringos I've built.
I think it makes the tuning a little less touchy.

Faraday's theory is from 1846.
You prefer Heaviside's from 1884.

You should know that Tesla and Marconi proved that Faraday is right and Heaviside wrong.

Which is true enough but has nothing to do with the topic under discussion.

You just saw the phrase "standing wave" in the post and in the link
and made the incorrect assumption the link was talking about what was
posted, and it isn't.

Most of us prefer information from the late 20th Century, by which time
how antennas really work was figured out.

> You should know that Tesla and Marconi proved that Faraday is right and
> Heaviside wrong.

You should know you are a babbling idiot stuck in ignorance and the late
19th Century.

Do you wear slip on shoes?

Hello folks.
I sense another entertaining exchange of postings is imminent. It would appear that Szczepan hasn't learned that it is wise to understand what he is posting.
Here's another quote from that web site:
"In AM work misadjustment of ATUs and other devices in the transmission line circuit can result in a severe mismatch that goes unnoticed."
Well, it made me smile .. a lot.

73 Ian.

Absolutely false! Maximum transmission efficiency occurs when the source im=
pedance is zero, i.e. zero losses in the source. Let's rewrite that above s=
tatement to make it valid.

Maximum transfer of available power occurs when the load impedance is conju=
gately matched to the generator impedance. Such a conjugate match at RF res=
ults in a resonant system in which the reactance of the load is neutralized=
 by an opposite sign reactance in the source.

I cannot imagine what your problem is with the 2 meter CushCraft Ringo Ranger. I have had the same one in service off and on since the late 70's. Easy to mount, easy to match, physically durable, priced real close to the cost of the aluminum. The J-Pole is popular now days but is not near the performer that the Ringo is. I have both! The Ringo on a tower is not a good idea because it brings up too many repeaters on a given frequency. Bad operating manners!
As far as the 12 element CushCraft Yagis are concerned I have a 440 & 2 M models and have found them to work just like the modeling programs indicate. There will be a "lump" on the pattern that is not shown in the model, presumably radiation from the Gamma match.

There are ways to improve on CushCraft products (Stainless Hardware!) but in the long haul, you generally get your moneys worth.

I am sorry you have had a bad experience with the Ringo but I don't think you really explained your problems.

A little more information would be a big help. There are a lot of really smart and helpful guys lurking here who have been very generous to me over the years.

Please back up & try again...

On 9/5/2012 4:17 PM, NM5K speculated:

> About 16.5-17 inches long with coax that has a .66 VF.
> It's not too critical.

Hummm.. Actually, being as the coax is used for capacitance,
the pf per foot would probably be more pertinent than the VF..
Seems like RG-8 is about 26 pf per foot??? I fergot..
And am too lazy to look it up.. :/
But like I say, it's not critical at all.. You could probably
be an inch off either way, and notice little difference in
tuning.

As I understand it, the basic Ringo antenna is a half-wave, end-fed vertical dipole. A gamma loop at the bottom serves as the impedance matching element.

The basic J-pole is fundamentally quite similar... it's a half-wave vertical dipole, end-fed. The common versions of J-pole use one or another variant of a shorted quarter-wave stub section as an impedance match.

These two antenna types should, in principle, have very similar radiation patterns (they're both half-wave radiators) and can have similar problems with pattern-disturbing "RF on the mast" and "RF on the feedline" (they're often grounded to the mast, and fed from a 50-ohm feedline without a choke). In some installations, the "RF where you don't want it" condition could cause the antenna's pattern to squint in directions where it doesn't do you all that much good, and have a weaker signal directly out towards the horizon where most of the repeaters probably are. In other installations (where the feedline or mast presents a high or highly reactive impedance) you wouldn't notice any problem.

The Ringo Ranger is a higher-gain antenna, with two vertically-stacked radiating sections and a phasing stub between them. It looks to me as if the two sections are 5/8 wavelength or a bit more. You'd get several dB more gain towards the horizon with this configuration, than you would get from a J-pole or an original Ringo.

The Ringo Ranger has no decoupling from the mast or feedline, and can suffer from the same sort of pattern-squint as the Ringo and J-pole.

The Ringo Ranger II adds a decoupling section (a length of feedline and a set of decoupling radials) which is supposed to prevent this problem, and it would probably have the cleanest and sharpest towards-the-horizon pattern of any of these antennas.

Posting-Frequency: posted twice monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been recently revived by an active moderation team. We are currently seeking suitable information, FAQ, and bulletin articles from the entire rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our newsgroup.

We are seeking a replacement maintainer for the following information bulletin formerly posted to rec.radio.amateur.* (and currently archived at http://www.faqs.org/faqs/radio/personal-intro/):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

One significant omission, requiring immediate updates, for this article |
is that it does not mention newer amateur radio newsgroups created since |
it was written, including: |

rec.radio.amateur.antenna |
rec.radio.amateur.boatanchors |
rec.radio.amateur.dx |
rec.radio.amateur.equipment |
rec.radio.amateur.homebrew |
rec.radio.amateur.moderated |
rec.radio.amateur.space |

We are willing to provide any technical support necessary to get this article updated and automatically posted again at a regular interval. This would include establishing contact with the original maintainer for any necessary permissions. We would prefer to seek a new, dedicated maintainer at this time, rather than start auto-posting the original article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to
rec-radio-info-request@panix.com.

A resonant antenna system may still produce a mismatch to the transmission line connected to it. One example is an electrically short whip antenna used on the lower ham bands. It can be resonated using a loading coil, but its radiation resistance may be only a few ohms -- which will produce a significant SWR on the transmission line when the whip is fed with 50 or 75 ohm coax.

```

You are talking about an *impedance* mismatch between the antenna and the Z=

```
0 of the transmission line and of course, you are correct. But in an ideal =
conjugately matched system, such impedance mismatches are irrelevant becaus=
e maximum available power is transferred, i.e. the *system is resonant* no =
matter what the impedance mismatch. That's why non-resonant antennas radiat=
e just as well as resonant antennas - they are both components in a *resona=
nt system*.

If we install 1/4WL of lossless Z0=3D27.4 ohm feedline between a 50 ohm tra=
nsmitter and a 15 ohm antenna, is there still a mismatch? The SWR on the fe=
edline is 1.8:1 but the transmitter sees a load of 50 ohms looking into the=
 feedline and the 15 ohm antenna sees a source impedance of 15 ohms looking=
 back down the feedline.

In an ideal conjugately matched system, the resistance of any resonant ante=
nna is indeed impedance matched to the *transformed* source resistance. In =
fact, the above 1/4WL of 27.4 ohm feedline can be replaced with an ideal 50=
/15 ohm transformer, thus achieving an impedance match, and all conditions =
in the antenna will remain the same.

The only question remaining is how far can we deviate from an ideal conjuga=
te match and still be satisfied with the results? That requires calculating=
 the losses in the system and losses are the enemy of system-wide conjugate=
 matches. In a system with losses, Walter Maxwell settled for a "one-way co=
njugate match".

I am trying to receive an am signal well below ground level in a metal server room, there is a coax feed up to the roof which I used and attached the standard wire loop that was supplied with the tuner, however when I attempted to tune into some stations I could only pick up a couple of local stations and wasn't able to receive the ones I was hoping for. when I dialed in the desired frequencies, all I was receiving was a tone, the tone changed in frequency/pitch depending on the tuners frequency. To check that I could receive the stations I took the tuner to the roof and attached the antenna directly and sure enough I could pick up the desired stations. My thoughts are that the coax is affecting the signal in some way, perhaps picking up electrical noise? any advise would be appreciated.

Rent a room directly under the roof.

Numbers please...
What make and model tuner?
What loop antenna?
What type of coax cable?
How many feet of coax?

The loop antenna that comes with most home hi-fi receivers is resonant in the BCB (broadcast band). If you add coax cable or twinlead to the loop, it becomes detuned and starts looking more like a short circuit. The barrier strip BCB connections on the back of the hi-fi are intended for a "long wire" antenna, and a decent ground connection. The required BCB antenna impedance is probably much higher than your coax cable, which means you'll need to build a matching network if you plan to use coax cable to the roof. You might do better with just the longest wire you can find that makes it up to the roof and beyond, if it doesn't pickup RFI/EMI from the servers.

If you're plugged into the "F" connector found on the back of some hi-fi's, that's for FM band reception, not BCB.

>however when I attempted to tune into some stations I could only pick up
>a couple of local stations and wasn't able to receive the ones I was
>hoping for.

That's because the loop antenna is acting more like a short than an antenna.

>when I dialed in the desired frequencies,

Why would you want to hear BCB AM radio inside a server room?

>all I was

>receiving was a tone, the tone changed in frequency/pitch depending on
>the tuners frequency.

If it's anything like the server farms that I occasionally visit, the
RFI/EMI from the high power switchers, servers, and thousands of clock
oscillators is sufficiently high that I couldn't even get a pair of
cheap FRS/GMRS radios to communicate across the building. I suggest
you consider streaming audio as a better alternative.

>To check that I could receive the stations I took
>the tuner to the roof and attached the antenna directly and sure enough
>I could pick up the desired stations.

Yep. You probably connected the loop directly to the unspecified
model radio. Try it again with an approximate length of unspecified
coax cable and it should fail similarly to your indoor test. Also
note that you're now outside what I suspect is a shielded room, which
should improve reception. For entertainment value, try making a cell
phone call from insider the server room.

>My thoughts are that the coax is
>affecting the signal in some way, perhaps picking up electrical noise?

Yes to both questions.

>any advise would be appreciated.

Long wire antenna or switch to streaming audio.

I think a Google on 'active antenna' might give you a lot more general information. Start here:
http://en.wikipedia.org/wiki/Active_antenna

They typically untuned (and hence fairly wideband).

An active antenna often consists of a short whip antenna, which functions as a high-impedance RF voltage probe. This is connected to the input of an amplifier which has a very high input impedance. The amplifier provides gain, and also converts the high impedance of the whip to a low impedance, which is suitable for connecting to 50 or 75 ohm coax feeder.

Of course, the amplifier has to be powered, and typically this is provided by a DC power unit located at the receiver end, which sends the necessary power back up the coax.

Note that one thing an active antenna must do is not to be overloaded by strong signals (which can be a problem if you have a local transmitter or two in your area).

But as I say, have a Google, and see what information it brings you.

```

Server room? Internet access? Many (most?) of the AM stations in my
area are now available through live streaming. Might check for the
stations you want.

I am sure you are too young to remember placing an AM radio on top of a CPU and running certain programs to produce music. Waltzing Matilda was one. I recall my 2 meter FM mobile rig, driving up to the building, hearing the noise from 20 ma. current loop to terminals. You are in the middle of a vast sea of digital noise! All your AC power wiring is conducting it everywhere.

I am not surprised at you hearing tones.

First, you need to have a battery powered radio so the AC wiring is a little further away from the receiver.

Second, you might want to try RG-6 coax. It's cheap and as I recall, double shielded. You will want to find a place to ground one end, only, of the coax to a building ground, not an AC outlet ground wire.

How close is your current coax to other signal carrying cables? Keep the coax as far away as possible. Never running parallel, if possible. And if crossing, cross at right angles.

Finally, does anyone else working there have a radio that is receiving properly?

IF nothing else will work, there is always FM.

Paul, KD7HB

Hey OM. These antennas are pretty simple, The instructions are on the web. Check the instructions against what you have and you should be able to get them to work by putting them together or making repairs. One is as easy as the other.

Jimmie

Thank You / Thank You / Thank YOU VERY MUCH!

I can make a loop out of some copper tube and I can use a old piece of RG 8 for the stub match and I have enough aluminum tube from another Ringo to make the mast 18' long.....

All I need to do now is take down what I have and modify it and put it back up.

THANK YOU!

Dummy ME! - I could have bought a used antenna analyzer at a hamfest today for $50.00 - MFJ that had no digital display and no UHF and NO POWER SUPPLY and no instructions.

I was told that I could have used it with a transceiver, turn the knob until it zero beats the frequency of the receiver and then use it to tune the antenna.

I probably messed up!

Then again - if it was $50.00 and didn't work and could not be repaired - it would have been $50.00 that could have been applied towards another antenna.

This is what happens when you try to help someone and when you try to

give something away to a friend..
It always happens that something is not right and that when it does not work as intended - even if several years later - I end up being the bad guy.

In fact - the Ringo listens real well - it just doesn't transmit - because the impedance / reactance is wrong.

I could have bought a good antenna analyzer last year for $85.00 and did not because a friend of mine wanted it and bought it for $65.00

I'm learning that amateur radio is a lot like stock car racing.
The only friends you have is the ones you brought to the track with you!
Once the Green flag falls - all agreements are off and it is a free for all.

Two approaches possible: (1) Disconnect the wire loop from the tuner and attach the coax to the connection points formerly used for the loop.

(2) wrap about fifteen turns of lightweight insulated wire around the loop that came with the tuner. Attach one end of this wire to the coax shield and the other end to the coax center conductor. (It's an RF transformer.)

You have no business on either of those frequencies.

This is Sal again. I don't know where my login data went.

I dropped out as club FD Chairman. It wasn't fun any more. I was so happy when I assembled the last of the material I needed to report to ARRL.

A man has to know his limitations.. :| chortle... :)

I was up at the dirt patch a couple of weeks ago, and my 80/40 antenna
is pretty much trashed.. And the coax was pretty much gone..
It started raining, so I left before I could do more investigating..
At first I thought someone stole it.. But then I noticed random
pieces of coax laying on the ground.. I think critters, probably
squirrels, must have ate it.. I'll have to look more when I'm
back up there later..
But I know I'm going to have to redo everything, including new
coax if I want to continue to jibber jabber on the radio when I'm
there.
I plan to go back up there around the end of October.
One reason I think it was squirrels, is they had been eating off
areas of coax jacket in the past.. I'd have to wrap chewed up areas
with electrical tape to keep the water out.
I may have to coat my coax with something squirrels don't like. :(

bloggerccc@gmail.com wrote:

> You have no business on either of those frequencies.

Depends upon where you are.

433mhz is a SHARED ham band throughout the world.

In ITU zone 1 and possibly elsewhere, there is a small allocation
of 433mHz for unlicensed devices.

There also is one at 315mHz, but that may be a different part of the world.

It is used for wireless doorbells, security systems, etc. Basicly low power
unlicensed telemetry.

If you look on eBay, you will find hundreds of the devices. A quick web search
shows the 433 mHz units sold in the US.

Geoff.

Thanks for all your responses!

First off, I am attempting to auto switch/scan between two frequencies
on AM. I have FM and internet streams sorted. The tuner is a Cambridge
Audio hifi tuner with an RS232 interface for scanning. I don't recall

the exact model number. The tuner can't be relocated as the server is controlling the frequency scan.

Obviously I didn't attach it to the FM coax input! I do have a small amount of common sense.

The coax cable was already installed, I assume it's standard CT100 75Ohm.

the loop was just one of those cheap plastic things they bundle with tuners.

somebody mentioned impedance matching, Thanks! I'm going to look into this if I can't already find a ready made 50-75Ohm antenna.

somebody else mentioned overloading with an active antenna....this is central London so there are all kinds of local AM stations....what kind of damage can be done??

again thanks for your input, you have given me something to work with.
:)

In London, I think the only two main medium wave transmitter sites are
Brookmans Park and Crystal Palace (although I do see a 200 watt 'London
Turkish Radio' in Lea Bridge Road - and there may be one or two others).
http://www.mediumwaveradio.com/uk.php
However, with luck, you are unlikely to find a MW transmitter next door
to your house - and certainly not a really high-powered one.

Adverts for commercial remote active antennas seem few and far between
on Google. However, you might find these of interest. The Wellbrook loop
seems promising. The nulls might be useful, but for all-round coverage,
you'll need to rotate it.

If it's not too much trouble, could you make an effort to determine
the exact model number? I couldn't find a model on their site that
has an RS-232 port for frequency control. Once the model number is
determined, we can then look at the rear panel to see what you're
working with.

While you're at it, it might be useful if you describe the path that
the antenna coax is expected to take on its way to the roof. Is it
metal conduit? Plastic conduit? Random run? Diameter? Numbers?

>The tuner can't be relocated as the server is
>controlling the frequency scan.

I beg to differ. RS-232 will go about 150ft at 9600 baud without
difficulties.

>Obviously I didn't attach it to the FM coax input! I do have a small
>amount of common sense.

Assumption, the mother of all screwups.
That which is most obviously correct, beyond any need of checking, is usually the problem.

>The coax cable was already installed, I assume it's standard CT100
>75Ohm.

Assumption, the mother of all screwups again. Look at the coax and get the numbers. Also, what kind of connector.

>the loop was just one of those cheap plastic things they bundle with
>tuners.

Yep, that's what I figured. They're resonant in the AM band and do not work with extension wires on the leads. If you're ambitious, you could tear the plastic loop antenna open, replace the fixed tuning capacitor with a variable, and experiment with different parallel transmission line lengths. However, I don't think it will work very well.

>somebody mentioned impedance matching, Thanks! I'm going to look into
>this if I can't already find a ready made 50-75Ohm antenna.

Hopefully, you mean 50 to 75 ohms, not 750 ohms. To get the antenna in this range, you need a 1/2 wave dipole. At 1MHz, that's 468ft long. You can shrink the antenna with loading coils, but the usable bandwidth will decrease to the point of uselessness. An active antenna might work.

However, I suspect all this design effort is a waste of time. The receiver should be able to hear stations with a minimal antenna. All you have to do is figure out where someone else went wrong.

>somebody else mentioned overloading with an active antenna....this is
>central London so there are all kinds of local AM stations....what kind
>of damage can be done??

No damage. The effect is called "blocking" where the front end transistors or FET's rectify the incoming signal and change the bias point to where the device no longer amplifies. Unless you have an AM broadcast station literally next door, it's not going to happen. Your antenna is too small and the field strengths involved are insufficient to cause problems.

>again thanks for your input, you have given me something to work with.

Exact model number please.

Hello,

The question I have pertains to feeding an MW AM broadcast antenna tower but also applies in the ham arena as well. Given the advantages of shunt over series feed (no base insulator, tower grounded (lightning protection), no lighting chokes/ring transformers required, etc) why has shunt-feeding of AM broadcast towers been used to-date in relatively few instances in the U.S.? The argument that the slant wire to the tower adversely modifies the antenna pattern doesn't seem to hold up in theory or practice. Thanks for your time and comment and 73s from N4GGO,

Slant wire to the tower?
There is an AM broadcast tower here locally (Netherlands) which uses
a symmetrical version of this feed. The tower is 1/4 wavelength high
and there is a triangle at the top supporting 3 wires running parallel
to the tower and connected to an isolated ring at the bottom, where
it is fed from an antenna tuner in a box at the bottom. The tower
itself existed before the AM transmitter and is grounded at the base.
(there was a VHF omni at the top as well, but it has been removed)

I think it is called a folded unipole antenna. Electrically it looks
like half of a folded dipole.

Without knowing what model you have, I looked at the AZAR 651 series.
http://www.cambridgeaudio.com/assets/documents/
AP309771Azur651TUsersManual-01English.pdf

All I see is 300 ohm connection for a loop AM antenna.
So, if you use an antenna on the roof, and 75 ohm coax coming down,
then a 75 to 300 ohm transformer into the receiver. I may even shorten
the leads on the 300 ohm side just to limit ingress.
Does the receiver make all the tones if you short the AM input with a
very short wire?
Mikek

Hello, and a slant wire at about 45 deg from the ATU to the appropriate
connection point on the tower is the classic shunt feed (it is
essentially one half of a gamma match that is used with dipole
antennas).  The folded unipole is the newer kid on the block and it too
is a shunt feed.  I appreciate the response but this doesn't address my
question of why shunt feeding has received so little use in the
broadcast industry considering how long the technique has been known.
Sincerely,

I had a plain Two Meter Ringo back in the 70s, before they came out with the "Ranger" versions. It worked well, but gain claimed was probably DBi rather than DBd.

I also have three generations of MFJ antenna analyzers. I don't know if they are overrated, but they are very handy. They save a lot of time compared to using a transmitter and SWR bridge to set up an antenna.

As I understand it, they work just like the typical "reflectometer" SWR bridge where you set forward power to full scale and read reflected power on an SWR scale. Their VFO has its output held constant over the frequency range, calibrated for the equivalent of the SWR bridge's full scale setting.

The early version Channel Jumper mentioned, probably had a frequency scale printed on the face. For critical settings, either a counter or a calibrated receiver would be needed. Later versions have a counter built-in, and the latest also displays antenna data on the LCD display.

If they rated a ringo using dbd, it would be zero.. Which doesn't
look too good in the ad's..  :|
So they use dbi to make for manlier gain figures..
```

Dunno, I'm pretty danged fast using just an SWR meter. But I already
know what to expect, how to quickly know if I'm long or short, etc..
All the analyzers do for me is verify what I already know from
looking at the SWR meter, which in my case is built into the radio,
assuming I'm on the Icom. :/
I like not having to carry extra gadgets..

I would agree with you - except for the fact that it does make life a lot easier when you are trying to get a antenna to work and you do not know what is wrong..

With a digital display it is as simple as putting the antenna together on the ground, sticking it on a pole someplace, using a feed line that is as short as possible - less then 1/4 wavelength is desireable when possible - I know at higher frequencies this is hard to do.

Turning on the Analyzer and reading the input.

Using a old style analyzer isn't as simple when you do not know the exact frequency you are tuning to...
So in the long run - I probably saved myself $40 - $50.00

A stub match question I forgot to ask is - should the end of the stub match at 1' 8 inches long be shorted on the end or open...

The web calculator I used said the Stub would be short if it was shorted and would be long if it was not - but that if it was not shorted you run the risk of the stub trying to radiate the power applied...

Open. It's being used purely as a capacitor.

I think CC just pulled numbers out of the air. Especially in the eairly days. Just looking at an old ad from 1974. They rate the 2 meter Ringo at 3.75 db gain. No refferance as to what. Also the 11 element was rated at 13.2 db of gain. The only antenna that does make sense is the 4 bay dipole with up to 9 db of gain. Atleast if you put all the dipoles on one side, it could have almost 9 db of gain over a dipole.

I did compair two differant 220 mhz 11 element beams to an 8 element quagi I

built from plans in the ARRL Handbook. The quagi was much beter than either
of the 11 element CC antennas.
The antennas were put on a 30 foot push up pole so it was easy to change and
compair them. Most of the testing was to a repeater about 40 miles away,
but the results were the same on other signals.

Common joke was the CC stuff was compaired to the Heathkit Cantenna in terms
of db gain.

Which was quite a bit shorter than the CC 214WB. The 214WB, which was better when you took off the marketing based "trigonal" reflector, still only made 11.91 dBd on a 14' 11" boom when optimized (based on your preferences).

BTW the maximum reasonably obtainable gain on a yagi with a boom greater than 1 wavelngth is predictable with the following equation -

G = 10 log (5.4075 B + 4.25) for B GT 1

Where G is gain in dBd and B is boomlength in wavelengths.

I worked this out in the early 90's from a database of over 100 of the best practical, buildable VHF/UHF yagi designs. Thanks especially to K1FO for all of his design work. His 432 yagis had the greatest effect on the numbers. W1JR thinks it's accurate, so who am I to argue?

I designed an extended version of the 214 that lets you re-use the useless extra reflectors as directors. This had a 17' 7" boom and would make 12.43 dBd at 144.2 with a decent feedpoint impedance of 21 ohms and F/B of 24 dB. This was used successfully at a friend's place for a 2 by 2 EME array. The antenna was tested at Central States and met the computer predicted gain exactly.

If you want crazy I have a 432 EME antenna that does 18.4 dBd (according to the model) which tested at 18.1 on the range. They said the range was too short to test the antenna. It was still the highest gain for a homebrew 432 ever tested at Central States.

Anyone that wants any 6m to 70cm designs can drop me an email. I've got lots.

tom

I like the K1FO designs. I had a 432 antenna by Rutland Arays that seemed to be a copy of the K1FO design. Several years ago I put up some new antennas and wanted to go withthe Rutland, but he had passed away and went with the M-Square antennas for 2 meters and 432 mhz.

From what I read, the Trigonal reflector was something that looked good for sells, but did little or nothing for that antenna.

Being Long or Short is not the problem - if it was simple vertical with a ground plane with no loading coil - like a whip on a automobile - yes - you would be right.

But when dealing with a Ringo - which uses a ring to adjust the capacitive / inductive and also uses a tuning stub match - each part of the antenna works against each other..

Even now, the antenna on the VSWR Bridge shows a 2:1 match!

But I figure the Ring is probably 9 inches too shot - if the ring is 7.5 inches in diameter and needs to be 10 and the stub is too short - if it needs to be 18 inches long and is only 6....

The Antenna Analyzer would tell me the Resistive / Reactive components and all I would have to do is match them and it would work on any one frequency.

This is the problem with the Ringo - why it is not broad banded. The main use where I live was by people who were installers of LMRS equipment that sold them along with a radio to fire companies and ambulances....

No problem even with loading coils. Or when using the various
matching systems. They all act fairly predictably.

>

Sure, it needs more inductance.
>

For a 10m ringo 18 inches would be about right with it tapped
about halfway. I think one I made used about a 20 inch dia turn.
But I didn't need all of it.

>

Sure.. But I can do it by sense of smell.. Plenty of practice.. :/

It should have about the same bandwidth as most any other
half wave. I've never noticed them to really show any less
bandwidth than other designs. But then again, I'm not sure
what you mean by not broad banded. That could vary depending
on expectations.

Yep, most have come to the conclusion they were kind of a waste
of metal.. I've got an old 2m "boomer" that has that reflector..

Linked below is a clip from "Radio Antenna Engineering" by Edmund Laport, which does show some pattern effects from shunt feeding a monopole. The FCC dislikes shunt fed radiators for AM broadcast stations (especially for directional arrays), as their skywave radiation patterns are inconsistent, and interference ratios are more difficult to predict.

Hello, and that identical diagram appears in my 1961 copy of Jasik's "Antenna Engineering Handbook" (McGraw-Hill Book Co.) in the chapter on medium-frequency broadcast antennas. In narrating the diagram (Fig 20-9) Jasik states, "Figure 20-9 shows typical variations in vertical pattern resulting from shunt feed. The radiated field from a shunt-fed tower is essentially the same as that from a series-fed tower of the same height."

The diagram only shows measured data for a slant-wire shunt fed tower rather than a comparison of that with measured data from the same tower being series-fed.

Apparently the FCC disagrees with Jasik. However I think the question from my original post has been addressed ("Because the FCC requires it"). Thanks, Richard. Sincerely and 73s from N4GGO,

\>Linked below is a clip from "Radio Antenna Engineering" by Edmund Laport,
\>which does show some pattern effects from shunt feeding a monopole.

And, if you'd like to refer back to Laport's original text in more detail, it's available as a free BitTorrent or HTTP download, or in an inexpensive printed form. I scanned a copy and converted it to PDF a few years ago, after I was able to confirm that it has reverted to the public domain.

You can get the PDF version from Lulu's servers, at

http://www.lulu.com/shop/edmund-laport/radio-antenna-engineering/ebook/product-17560294.html

If you want a printed copy, Lulu will do a "print on demand" at their usual per-page-and-cover cost (I've waived any royalty, and they don't charge a commission - this helps keep the cost down):

http://www.lulu.com/shop/edmund-laport/radio-antenna-engineering/paperback/product-188778.html

If you'd prefer to Torrent it, go to my own server to find the control file:

http://snulbug.mtview.ca.us/books/RadioAntennaEngineering/

```

Depending on the distance (which might mean an unacceptable added expense), you could run PVC. I put in a 10 ft satellite dish in the mid 1980's, running all the cables in PVC because they needed to be buried for appearance. (The stuff was called "direct burial, but ... I'm a skeptic.) The point is that it was still fine after about two decades when I decommissioned it about five years ago in favor of digital cable. Both ends opened down to keep moisture from dribbling in but yet letting the inside "breathe" with temperature changes.

One caution: Just because the cable fits into the coax, you may not be able to pull the whole length due to internal drag friction. I had to cut my PVC and thread the cables throught the first section, then a PVC union and then the second section. Finally, I glued the cut ends into to the union. If you use big enough PVC, you won't have my problem.

Channel Jumper-

You can get parts measurements for the various Ringo antennas at the CushCraft website (Now part of MFJ!). For the Ten Meter version, <http://www.cushcraftamateur.com/Product.php?productid=AR-10>. A user manual is available by clicking on "AR-10 Downloads". I do not see a Stub length given for the AR-10, but the AR-6 manual has a chart.

The AR-10 manual's specification says that gain is 3 dB "Ref.

Quarterwave"!

I used a chunk of circuit board material about 5 mm thick. I don't recall where I got it or why it was so thick but it worked very well for a short period. Can you go to a surplus store and root around in their junk boxes for old circuit boards? If you spray them with electrical varnish after making the connections, you should get some time before failure.

I don't think that would work.. The coax is not running to
a building or anything. I was feeding 80/40 dipoles, with
the feed point between two oak trees, and the coax led over
to one of the trees. I'd just run it out to wherever I was
operating, usually my stone bench. I had about 100 feet of
RG-58..
When I left, I'd just roll the coax up and hang it on a tree
branch. I got about 5 years out of that setup before the
coax went kaput.
One thing I might consider is installing a box or something
to store the bulk of the rolled up coax away from critters.
They still would be able to eat on the part leading to the
antenna, but at least the bulk of it would be fairly safe.
What was weird this time was none of the rolled up coax
was hanging on the tree, and it was broke or unconnected from
the antenna, and only a few little pieces on the ground.
Some varmint might have dragged it off into the woods, but
like I say, it started raining. So I left, and will have to
look for other pieces when I go back up there.
Someone may have stolen the bulk of it..

But I expect it's all basically ruined, so I will be needing
to replace it all. Luckily I use only the thin stuff there,
so cheaper than buying the usual 213 that I use here at the
house. 213 is direct burial.. But it's too heavy for what I'm
doing up there. Too pricy to leave out also, being it's basically
thief bait hanging on the tree branch.
I haven't bought any coax in a few years, and expect sticker
shock due to the price of copper these days.
I've got lots of spare runs of RG-8, but not sure if I have
any rg-58 left or not.. Like I say, the RG-8/213 is too heavy,
even if I wanted to risk leaving it there.
I'd also have to rewire the antennas with thicker wire to support
that heavy stuff and be able to keep tension on the antenna
wires to avoid the droops.

It's in the manual.. Was about 16.5 inches long with the RG-8
they use. They don't give the dia for the single turn coil,
but I've built a few of those, and used 18-20 inches or so dia.
Not real critical being it will be tapped appx mid way for a coil
that diameter. 7.5 inches dia is too small for 10m. Even 10 inches
would likely be too small unless maybe you tapped it near the end,
using almost the whole coil. I don't think I'd make it any less
that 15-16 inches dia.

I overlooked the stub in the manual I downloaded.  Now I see it in the
Ring Assembly Parts, Key FF.  It is 16 5/8".

Ring diameter is listed as 13" in a chart at the web link above.  I do
not see size listed in the manual, where the ring is shown as two
similar pieces bolted together.

Yep, I see it now.. I was thinking it was slightly larger than that,
but maybe the original AR-10 I had was only 13 inches across.
They show the 6m version using the same part.. From the diagram,
it looks like about 2/3 of the turn is used on 10m.
Also, if I remember right, the 6m version used no coax cap for
tuning. I was looking at the 6m ringo PDF the other day.

315 mHz is in a band used by the US military, where they are already "tolerating" a fair amount of intrusion from garage door openers and similar devices. I was privvy to some US Navy classified message traffic that discussed the issue. (It was classified because it identified specific frequencies and such are always classified.)

This fellow, "new to the field," as he self-indentifies, seems like a source for interference more than learning. A bit risky.

I agree. However, you might approach "droop" in other ways.

Depending on the height at which you want to place the feed,
you could potentially add a non-conductive span of nylon line
above, supporting the weight of a heavier coax. (I have several
"quick rigs" for dipoles; one of them includes a span line with
pulleys along the line. One I get the span line up, I can begin to
haul conductors aloft with other line. Reduced element stress.)

The success of this depends on how tall the trees are and how
easy/difficult it is to get into them.

It depends upon where he is. Outside of the US, the US military is a guest,
and has no authority to use those frequencies. Certainly no claim.

There was an international incident here in Israel a few years ago when
a foreign miltary ship with a new radar system parked off the coast of
Lebanon with a new radar system which used the downlink frequency for our
local DBS system.

Within a week, the radar system was shut off, and they ship left.

So just because a military uses a frequency in their home country does not
mean that anyone elsewhere can not use it if it is legal, nor can that
military tell them to stop.

Geoff.

I thought they were internationally allocated worldwide ... that is, certain bands like 225-400 were reserved for government use, exclusively. (I guess even so, government could certainly be non-military, too.)

Thanks for the info.

Overcoming my ignorance one day at a time,
"Sal"

Ringo antenna - like *all* half wave antennas - don't want the mounting mast lenght of 1/4 wl and odd multiples. So be careful. Many people said ringo antenna is bad, no resonance, etc... because of this.

Changes followed by "|".

```
After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/
d7d337db35f23326

the rec.radio.amateur.moderated Moderation Team had decided to consider       |
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup.  After a successful trial         |
period (90 days, through early July 2009), we decided to adopt this           |
change permanently.                                                           |

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

  http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date.  In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved.  We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.

Please direct any comments, questions, or criticisms to
rec-radio-amateur-moderated-request@panix.com.

Ok, so what I did was take the antenna apart, add another couple of feet
and made it 16' long.
I shorted out the stub match at 19 inches long.

SWR was about 5:1

So I tried lengthening it to 18' - which did not improve the SWR much.

So I put it back at 16' and I cut the stub match off at the solder point
and I stuck it up 30' in the air and the SWR was 1.1 : 1 at channel 23
and was 1.25 : 1 on channel 1 and was 1 : 1 on channel 19....

Since the person I put it up for only has a 23 channel radio, and since
he only uses channel 19 - that was all he cared about...

Technicially it says it is good for about 1.5 : 1 on any frequency -
hence getting it closer then that was a real accomplishment, and
although I know a little about antenna's - this one had me stumpped.....
Thanks everyone.....

Not that it maters but another ham and myself have been licensed for 40 years.

We ran across somethng the other day that we had not seen before. We live about 10 to 15 air miles apart. I have a vertical dipole at 35 feet on a tower. He has 2 differant FM rigs and vertical dipole wire antenas in his attic about 50 feet apart. I can work him direct on 6 meters with him mobile in his drive way. A couple of days ago we could work with his attic antenna.
He built another antenna , so he has two antennas and rigs. A Midland and GE comercial unit that puts out 40 watts each. I check the sensitivity on a HP 8924C and they both seemed to be as good as a Midland I was using.

It rained and now he can not hear me, but I can hear him fine on either rig and antenna of his. I switched to an Icom 706 at 100 watts out and and checked the reflected power is about 2 watts. At this time, he could tell when I was transmitting ,but not understand me. We were co-ordinating over 2 meters.

I also switched to an OCD antenna at 50 feet and could hear him. The internal tuner on a 746 pro tuned it,but he could not hear me on that either and he was about S-5 on the meter.

Do you think we have discovered one way shingles ???

Anyone else seen anything like this ?

Subject: 14.070/7080 Dipole dimensions
From: ai8o <ai8o@lexcominc.net>
Injection-Date: Wed, 19 Sep 2012 16:26:28 +0000
Content-Type: text/plain; charset=ISO-8859-1
```

I am rebuilding my HF station after a lightning strike.

I plan on doing a lot of BPSK31/BPSK63 work.

I want to build a dipole optimized for use on 14070/7080 KHz, and 3581 if possible.

These frequencies are not exact harmonic multiples of each other.

A dipole cut for 3581 operating in 20 meters would be 180 khz off resonance.

Would this be too much of a mismatch if I do not use an antenna tuner?

I want to avoid using an antenna tuner.

Would optimizing the antenna for some nearby or intermediate frequency be a good compromise?

Would an antenna just using 14070/7080 be a better solution?

I am located in EM95vs.
 What kind of antenna pattern would get from the following antennas:
350-170 degrees mounted 32 feet above ground at center or 60-240 degrees mounted 45 feet above ground?

More likely you've discovered a nearby lightning strike
and now his RCVR front end is blown.

There are no antenna preamps. All our rigs just go from the output up some coax and to the antennas.
The rigs are just older comercial Midland XTR and GE MLS. They have been reprogrammed to 6 meters.

He has two seperate antennas and rigs. I had just checked all rigs involved in the last two weeks with an HP 8924c test set and all were putting out 30 to 40 watts and the receivers would open the squelch at under .3 uV. I don't recall the exect valuse, but they met the origional specs.
I know the rigs are on frequency to less than 100 hz. Also all were verified that the receive and tramsmitt matched what we have the chanels set for.
The midlands were all programmed off the same programming file and computer.

I do not recall any thunder storms in the area. If it blew the front end, it would have had to do it to two rigs and the antennas are in the attic.

We will check out the sensitivity again at the first chance.

r.=20

Even multiples don't work for single-wire dipoles. Only odd multiples work.=
 A resonant dipole cut for 3581 would also be resonant around 10.7 MHz, 17.=
9 MHz, and 25.1 MHz. It would be *anti-resonant* around 7.16 MHz, 14.32 MHz=
, 21.5 MHz, and 28.7 MHz. Anti-resonance is worst-case for coax fed antenna=
s.

You could build a fan dipole with a separate dipole per band or you could b=
uild an 80m dipole with traps for 40m and 20m.

A standard G5RV works well on 80m, 40m, and 20m with a tuner. A ZS6BKW coul=
d be optimized for 40m/20m operation by playing with the dipole length and =
matching section length.

I recently acquired an Icom IC-706MKII radio. My plan, before I get my license and begin transmitting, is to use the radio for a general coverage and shortwave receiving.

The IC-706 has two coaxial antenna ports and I am looking for antenna suggestions for monitoring shortwave. I live in a house and have the ability to string just about anything up.

Looking for recommendations for a great all-around shortwave antenna that will connect to the coaxial port.

The usual cause when this happens to me is an frequency offset in either my in rig or the other operators. Are you sure that your rig isn't set accidently to some type of TX shift. There are two rigs at the other end and none of them can hear you.

It is doubtful the frequency has been changed in any way. The rigs are comercial FM units and the only way to program them is with a computer connection. Once set, all you can do is change the chanels on it. I know the other ham did not change his as I have the programming cable. All the Midland units were programmed using the same program file at the same time. They worked fine before the rain. The frequencies were even verified with a service monitor after they were programmed. I also used an Icom 746pro and can read the frequency on that, and I did not see the display change frequencies. At 100 watts, he could just hear me in the noise where before the rain we were full quieting with the 40 watt units.

Now that is an idea I have not explored.

A six meter repeater was just put on the air about 5 miles from him and sometimes there is a power pole that generates enough noise at the repeater site it desenses the repeater receiver. We are working with the power people now.
We do not hear it on the repeater, but an AM receiver pickes it up very well.

I am sure it is not this noise as it is too far away, but he may have a local source that is causing a problem.

Just about anything will work. Down to a simple random length of wire
stuck in the center conductor of the HF port, and draped around the
living area or yard.

As NM5K said, just about any wire stuck in the HF antenna port will work.
As you plan on getting a license, you may want to look at what is often called a Carolina Windom. It is a wire about 130 feet long, about 45 feet from one the wire is cut and a 4 to 1 balun is put in. From this, about 20 feet of coax comes down, then a bead type choke is installed, and from there enough coax to reach into the shack. The 20 feet of coax should be vertical if possiable. This antenna will often need a tuner to transmitt with, but for receiving, it will work very well without one. I use that type with my Icom 746 and it works very well at 50 feet.
I have also used it at around 30 feet with a 706 and it works ok.

Now the shingles have dried out we can hear each other on all the radios and antennas. I know nothing has changed as the radios need to be programmed by computer and I have the cable.

The distance is just under 10 miles so we should be almost radio line of sight. The land between us is rolling hils. Going from about 600 feet at the lowest to 900 feet at the highest.

Yes. Water is able to damp completly the weak yours waves.
His waves are emitted close to the wet shingles and are damped a little
only.

Thanks! it is the Azur range, I don't go to London often so I can't
check the exact model right now....thanks for spotting the 300 Ohm in,
the white text on the unit was worn away. when I shorted the input the
tone was not present. I'm going to go back in a couple of weeks and get

this sorted. Thanks!

I've used this one for several years with good results:

http://www.universal-radio.com/catalog/sw_ant/2205.html

The Par Electronics EF-SWL is an end-fed short wave antenna optimally designed for 1-30 MHz reception. The radiator is 45 feet of genuine #18 black polyethylene coated Flex-Weave wire.

This antenna wire is very strong yet can easily be coiled like a rope for portable work. The UV resistant matchbox houses a wideband 9:1 transformer wound on a binocular core. Unlike other transformers, external stainless studs on the matchbox allow the user to configure the primary and secondary grounds for best noise reduction at their particular location. Examples are given in the manual. Output is via a silver/teflon SO239 UHF connector (ready to accept a PL-259). Lead-in coax cable is not provided.

The radiator also attaches via a stainless stud allowing it to be removed, or replaced with a different length radiator for experimental purposes. The newly redesigned snag-proof insulators are very strong. The included manual shows typical radiation patterns for selected frequencies through out the HF spectrum. (This is a receive-only antenna).

Order #2205
List Price: $75.00
Your Price: $72.95

Spend your money once and spend it right.

My first antenna was a G5RV which is a poor antenna and is a non
resonant antenna, that does work on 20 meters, but only 20 meters.

My second antenna was a Solorcon / Antron A99 Vertical - which works
well for 10 / 12 / 15 and 17 - with my internal antenna tuner.
I do not like external antenna tuners.

Your technician class license will not allow you to operate anything
lower then 10 meters phone 28.300 - 28.500 MHz USB....

If you are going to spend good money on a resonant HF antenna - that
does not require a expensive antenna tuner - you would want to purchase
a Barker & Williamson BWD 90 - folded dipole.

I'm not sure if you are going to be happy with your combo HF / VHF / UHF
transceiver. It lacks good filtering and doesn't do anything especially
well - other then it affords you the opportunity to use it in more then
one band or mode...

The price of the B&W will probably be one third of what you spent on the

706..

For listening, it doesn't matter how high you put it up, as long as you put it up and use the best possible coax to feed it.

Two meters / 440 - you would want to purchase a Diamond X 500 and get it up as high as you can and feed it with the best possible coax such as the Belden 9913F7 or LMR 400

Summary: Recruitment announcement for ham-radio-related FAQ articles
Keywords: FAQ, Intro, amateur, ham, radio, recruit, recruitment

Posted-By: auto-faq 3.3.2 beta (PGPMoose V2.0, Perl 5.005)
Archive-name: radio/ham-radio/recruitment
Revision: 1.2 2009/11/25 14:41:01
Posting-Frequency: posted twice monthly
```

URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been recently revived by an active moderation team. We are currently seeking suitable information, FAQ, and bulletin articles from the entire rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our newsgroup.

We are seeking a replacement maintainer for the following information bulletin formerly posted to rec.radio.amateur.* (and currently archived at http://www.faqs.org/faqs/radio/personal-intro/):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

One significant omission, requiring immediate updates, for this article |
is that it does not mention newer amateur radio newsgroups created since |
it was written, including: |

rec.radio.amateur.antenna |
rec.radio.amateur.boatanchors |
rec.radio.amateur.dx |
rec.radio.amateur.equipment |
rec.radio.amateur.homebrew |
rec.radio.amateur.moderated |
rec.radio.amateur.space |

We are willing to provide any technical support necessary to get this article updated and automatically posted again at a regular interval. This would include establishing contact with the original maintainer for any necessary permissions. We would prefer to seek a new, dedicated maintainer at this time, rather than start auto-posting the original article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to rec-radio-info-request@panix.com.

You just showed that the off-resonant antenna accepts *more* power than
the resonant one. That is not a "sharp peak."

John

You used a fixed 100V source. If you can do that, I can use a fixed 1A
source. In that case a resonant antenna of 62.8 ohms feedpoint
resistance will radiate very nearly 62.8W. An antenna with a feedpoint
impedance of 62.8 + j50 will radiate very near 62.8W.

There is no sharp peak in the power radiated whether at resonance or
not. The definition as it stands is incorrect.

> You used a fixed 100V source.

Let's modify the definition until you agree with it. How about?

resonant antenna [=E2=80=B2res=C2=B7=C9=99n=C2=B7=C9=99nt an =E2=80=B2ten=
=C2=B7=C9=99] (electromagnetism)
An antenna in which there is a peak in the standing wave energy on the ante=
nna at a certain frequency during receive when configured as an unloaded pa=
rasitic element using a constant power, variable frequency source for the i=
ncident RF fields.

Would you agree that that energy peak indicates antenna resonance?

If you have to ask, then you are just being an asshole as usual. You
always want to have an argument whether you are right or wrong. That's
why I referred to wrestling a pig. Go screw with somebody else, pig.

Only a perfect person never makes an incorrect statement.

I gave an example where that definition applies to a conjugately matched no=
n-resonant antenna. Of course, all conjugately matched antenna *systems* ar=
e resonant whether the antenna is a resonant or non-resonant length. Seems =
that definition has the same flaw as in Reflections, by Walter Maxwell (SK)=
. Where he said, "My antenna tuner really does tune my antenna", he probabl=
y should have said, "My antenna tuner really does tune my antenna system." =
The definition should IMO also eliminate the word "sharp" from the definiti=
on. A resonant 1/2WL dipole does have a peak but it isn't sharp because of =
the broad bandwidth.

The definition of a "resonant antenna" *should* exclude non-resonant antenn=
as just as the definition of a "red car" should exclude non-red cars. A non=
-resonant antenna that is conjugately matched meets the definition of a res=
onant antenna. That seems to be ambiguous at best and at worst, a contradic=
tion. Updating the definition:

resonant antenna (also applies to a conjugately matched non-resonant antenn=
a) -
An antenna for which there is a peak in the power radiated or intercepted b=
y the antenna at a certain frequency, at which electric currents in the ant=
enna form a maximum current standing-wave pattern

So much for the myth that resonant antennas radiate better than non-resonan=
t antennas. Consider the following two examples without transmission lines.

50 ohm Source---50 ohm load

100+j100 ohm Source---100-j100 ohm load

Which system has the most efficient power transfer efficiency?

Has anyone ever considered that if the coax is disconnected from a center-f=
ed half-wavelength antenna, the antenna is no longer resonant and could ins=
tead be used for a non-resonant guy wire at that frequency?

Hi all

Problem exists how to get reliable insulation to split driven element and support rod which is exposed to RF voltage ?
Fiberglass is told to be sensitive creating conductive coal brigdes which creates true resistive short at driving point ? (at least one fiberglass tubing is done so... gap was 2 inches)

How to improve insulation ? Ptfe-shield over fiberglass rod, heat shrink tubing, varnish layer ?

tnx oh6io

The traditional approach is to use glazed ceramic insulators, I
believe.

Such a problem is going to come from one of two things:

Too much power for too little separtion and arcing; use wider spacing and
less power.

Accumulated filth and moisture leading to leakage leading to carbonization;
heat shrink tubing or tape like Coax-Seal to keep the path clean and dry.

I'll leave the specifics of your question to the experts.

But, worth mentioning is that once you have selected a material, plop some
in a microwave along with something like a a container of water.  Then see
if your insulating material stays cool.

Which is valid at the microwave oven frequency. Might be relevant at
HF, or more likely, not.

Assuming power of about 1 kW and a HW dipole (say 60 Ohms), the
voltage will be about 350Vp. I can hardly imagine that a plastic gap
of 0.05m will degrade to failure because of tracking.

Make sure you have UV resistant rods, and/or add some layers of UV
resistant (marine quality) coating.

# Which is valid at the microwave oven frequency.  Might be relevant at
# HF, or more likely, not.

# tom
# K0TAR

I'm sticking with the test being relevant at HF.
```

A material that does not heat up at microwave, would be unlikely to heat up
at HF.

At any rate, the test can be done for free.

Actually, a material can be perfectly fine at microwave frequencies and
bad at HF. And vice versa. The microwave oven test should only be
considered a *very rough* indication of material suitability.

73,
John

On the other hand, if the original poster is attempting to drive this
antenna off-resonance, with open-wire feedline and a wide-
impedance-range transmatch / "antenna tuner", then it's entirely
possible that the feedpoint will sometimes be "looking into" a much
higher impedance, and that a matched drive will result in very high
voltages at the feedpoint.  Even a coax-feed antenna might have this
problem, I suppose, if the split element is being driven by something
like a delta match which has a relatively high impedance-
transformation ratio.

From what I see in a short Google-search, fiberglass *can* be
hygroscopic, depending on what resin was used to bind the fiberglass.
A fiberglass rod which was made with a somewhat-hygroscopic resin
(e.g. polyamide) might tend to behave badly in the face of high RF
voltages, whereas a rod made with a non-hygroscopic resin might be
fine unless dirty or wet.

Hello Dave,

Thanks for de addition. During the simple voltage calculation my mind said: "what if VSWR is really bad".

With 1 kVp over 0.05m I would not expect problems. You are right, Polyamide (Nylon) is bad for RF and as far as I know, isn't fully UV resistant without additives.

Once I had a nylon bolt in the field of a tuning capacitor running close to breakdown over about 3mmm. The bolt produced lots of smoke within some seconds and broke down. Changing from PA to PE solved the problem.

Assuming 50% glass fill factor and effective loss factor of 0.2 (so Q of the glass/PA composite material is just 5), I would expect a dissipation in the range of 4 Watts at 1 kVp and 10 MHz in a 1.5 Inch thick massive rod. Maybe Kba can provide us some additional info on the working voltage across the gap (and frequency).

When using epoxy or polyester fiberglass, loss will be significantly less.

Care to suggest one or two examples of materials where RF losses are
higher at HF?

Summary: Short reminder for unmoderated newsgroups that crossposting is permitted
Keywords: FAQ, ham, amateur, radio, moderated, unmoderated, crossposting,
permitted
Bytes: 3851

Posted-By: auto-faq 3.3.2 beta (PGPMoose V2.0, Perl 5.005)
Archive-name: radio/ham-radio/moderated/crossposting
Revision: 1.2 2011/11/02 04:08:53
Posting-Frequency: posted twice monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/
d7d337db35f23326

the rec.radio.amateur.moderated Moderation Team had decided to consider |
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. After a successful trial |
period (90 days, through early July 2009), we decided to adopt this |
change permanently. |

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those that have been created consistent with the suggestions in "So You Want to Create an Alt Newsgroup" at:

  http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either "radio.amateur" or "ham-radio" in their names, including uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved newsgroups up-to-date. In case we have overlooked any, and a submission is rejected in error as a result, the rejected submitter can E-mail us at our administrative contact address (in the signature at the bottom of this article, and the default Reply-To for the rejection message) requesting that it be added, and that the article be approved. We may still choose to reject articles crossposted to any alt.* newsgroup with an inappropriate name, including obscene language, embedded name-calling, or encouragement of unlawful conduct.

Please direct any comments, questions, or criticisms to rec-radio-amateur-moderated-request@panix.com.

```

I have had an 80 meter loop running around my house at a height of 35 feet now for 5 years. It was fed with a 75 foot section of 450 ohm window line. This served me well during this time. I know very little of antenna theory. I do know some electronics and repair my own transceivers and amplifiers.

I wanted to do a little improvement to this loop to stop the thing from changing tune every time it rained or snowed.

A fellow ham urged me to use open wire 600 ohm line to stop this detuning from happening and to improve my losses with this antenna.

I already felt I had a pretty good antenna because it really lowered my receiver noise over a dipole that I had originally. Anyway, two days ago I finally did the work to put up a 600 ohm line using #14 insulated house wire and spacers from www.73cnc.com.

I was shocked to see my antenna change tune radically. I thought I had made a mistake and was going to have to replace the open wire line with the 450 again. I was worn out after the day of changing this line. So I spent the next day using the antenna anyway. My VSWR on 75 meters had gone from 3 to 8. Yikes. However, all the higher bands looked a lot better. 15 and 10 meters showed an almost perfect match. The antenna became much quieter. My friends on 75 said they heard no difference in my signal strength even with the 8 to 1 VSWR.

I have an Imax 2000 that I use for 15 and 10. This antenna always showed an increase in signal strength on those bands over the loop. Now the reverse is true. I hear signals on the loop that are buried in the noise on the Imax. In 1 short hour I worked Cuba, Belfast, Nurenburg, and California getting great signal reports from them all and seeing beautiful S meter readings from them.

I cannot explain this effect with any kind of theory. I simply don't know antenna theory. But it happened. My friend cannot explain it either but he tried using open wire feeds 30 years ago and will not use anything else.

Thanks for all comments, ... some new approaches have arisen... to eliminate possible risks and troubles before they exist...

This problem is dual, both electrical and mechanical as insulator in the element gap is under quite high mechanic stress...
This is future OWA antenna split driven element... will be used at HF...

This previous fiberglass problem wasn't instant, it developed slowly after several years of succesful use (and weather effects, moisture etc.) so probably the reason was only the moisture, dust and dirt layers in the inner surface of the insulator.
Insulator was round fiberglass tube of 65mm diameter and around one meter long, used as center of 7MHz antenna feed element (60mm diam.), the outer surface of the tube was weather (and UV) protected and water proof, but the 5 cm gap inside the tube was not entirely though element ends were not in open air... some moisture do condensate always inside the element... I guess...

Measured impedance was quite low, 25 ohms resistive near resonance, so probably voltages have been also low at one kw power level.

I cannot tell the exact fiberglass grade that was used, probably it was green FR4 or other strong quality as mechanical stress was high in the insulator and long and heavy 7MHz element halves loaded the insulator center.
This fiberglass insulator tube finally got to a ohmic short and didn't recover.

Later this insulator was replaced with another type and problems disappeared.

. . .

Now one other future split driven OWA antenna has been under plan ... but there are the same mechanical stress problems as element center gap should (?) have center support rod but it exposes also to all weather effects... in this case element diameter will be 25 mm...
So insulation in the gap should be good but material should be also something capable handling bending moment of the element halves...

Now the latest plan is try to move the mechanic load away from the center support rod to element support plate which could be much longer in length... then the element center stress is expected to be lower across the gap...

Then also the element clamps have more separation as this support plate is also again FR4...
Secondly the element halves will be insulated from the clamps so there will be less risk of this FR4 plate becoming conductive...
Insulation between element and clamps could be thin straps of teflon sheet...

Best might be if the fiberglass center support rod can taken totally out or be of round teflon bar... good insulator, low friction, probably air particles etc. don't stick on it easily...

Teflon feels tough but elastic, so in the stress point it's not much use, but probably functions as a vibration damper in the gap... assuming the element support plate does not transfer element end bending effects due to wind load directly to element center gap...

Anyway it's going to be interesting to see how these precautions will actually work... in both at mechanical and electrical reliability... hopefully in both.

tnx oh6io

In a past life, I helped design marine radios. As others have
mentioned, there are different flavors of fiberglass, some of which
are not really suitable for outdoor or high humidity applications.

Instead of trying to fix fiberglass, you might consider machinable
glass ceramics.
<http://www.matweb.com/Search/MaterialGroupSearch.aspx?GroupID=301>
Something like material:
<http://www.matweb.com/search/datasheet.aspx?matguid=848bdecf89b74ef986925162e6a6255e&ckck=1>
<http://www.corning.com/assets/0/965/989/1081/1397D5E7-018E-4CF4-A34C-6814B815BCAC.pdf>

It's sufficiently strong to handle antenna elements, but was also somewhat brittle. RF characteristics are superb. 9.4Kv/mm is not going to arc. However, you won't like the prices. A 1" dia 6" long rod will cost you $150.
<http://www.astromet.com/MacorPriceSheet2010.pdf>
For ham radio, nothing but the best.

Otherwise, there's always the traditional dry pine dowel soaked in bees wax.

Well, hmmm...
There seems to be several alternatives to fiberglass... and several
grades of it...

Just thinking of how glass ceramics may behave under bending force...
Element center gap is under very small vibration (wind load) and element
static load stresses the insulator center... it bends slighly depending
how elastic is the material...
Fiberglass have some elasticity... it's not brittle... on the other hand
there could be support limiting the bar bending or the element halves
might have more than two clamping points... so the center gap would
be steady...

Actually I had in mind using extra varnish layers on fiberglass after
processed to diameter and then boiling it in bee wax...
This is still the plan b or c.

tnx oh6io

Tracking (forming of conductive (carbon) path) is mostly a slow process that may take years to develop to failure, so this sound strange (if creepage is the root cause).

> Insulator was round fiberglass tube of 65mm diameter and around one meter long, used as center of 7MHz antenna feed element (60mm diam.), the outer surface of the tube was weather (and UV) protected and water proof, but the 5 cm gap inside the tube was not entirely though element ends were not in open air... some moisture do condensate always inside the element... I guess...

This changes the story when moisture can enter the inner side of the tube and may stay there. I assumed you used a massive rod for mechanical strength. At the inner side you don't have the cleaning effect due to rain, wind, precipitation, etc. Could there be salt built-up (due to seeping water that evaporates slowly)?

You mentioned it is 1 m long, that is really a large creepage distance! Assuming about 5mm wall thickness and fully conducting inner side of the tube, radial field strength (350V) will be in the 50V/mm range, well below permissible levels to avoid insulation failure at MHz frequencies in FR4 material.

It would be nice to inspect such a failed tube to figure out how the tracking took place, because I have now idea.

Besides mechanical cracks that may provoke solid insulation breakdown,
carbon trace forming (tracking) over wheather exposed plastic surfaces
is the most likely problem, so I think you should try to maximize the
creepage path. As E-field strength in the insulation materials will be
low, you don't need low loss materials.

Thanks for sharing the info on the insulator failure!

>Just thinking of how glass ceramics may behave under bending force...

Machinable glass ceramic insulators don't behave... they break. They're great under compression but miserable in tension. So-so in torsion. All you have to do is make the insulator stronger than the element it supports. If there's excess force on the element, the aluminum element will bend rather than the insulator will break.

>Element center gap is under very small vibration (wind load) and element
>static load stresses the insulator center... it bends slighly depending
>how elastic is the material...

I don't expect wind vibration to be much of a problem. The forces are rather small compared to a flock of overfed birds landing on the elements or the wind blowing at hurricane force. With a brittle insulator, an impact with a flying hard object is a real danger.

>Fiberglass have some elasticity... it's not brittle... on the other hand
>there could be support limiting the bar bending or the element halves
>might have more than two clamping points... so the center gap would
>be steady...

You haven't supplied any numbers or dimensions, can't do any calculations.

I don't think you'll have much trouble with the static loads (including the birds). The wind loading might be a problem depending on design.

Bees wax won't work on fiberglass.

>tnx oh6io

Perhaps if you build something really disgusting errr... innovative, which balances some of the tension on the insulator with a little compression, try building the yagi elements using wires instead of tubing using a "cage". The "cage" will increase the effective element diameter (thus increasing the antenna bandwidth). The "cage" will also supply some tension to the insulator, which will balance some of the tension.

Oops. That should read:
The "cage" will also supply some compression to the insulator, which
will balance some of the tension.

> A fellow ham urged me to use open wire 600 ohm line to stop this detuning from happening and to improve my losses with this antenna.
>
> I already felt I had a pretty good antenna because it really lowered my receiver noise over a dipole that I had originally. Anyway, two days ago I finally did the work to put up a 600 ohm line using #14 insulated house wire and spacers from www.73cnc.com.
>
> I was shocked to see my antenna change tune radically. I thought I had made a mistake and was going to have to replace the open wire line with the 450 again. I was worn out after the day of changing this line. So I spent the next day using the antenna anyway. My VSWR on 75 meters had gone from 3 to 8. Yikes. However, all the higher bands looked a lot better. 15 and 10 meters showed an almost perfect match. The antenna became much quieter. My friends on 75 said they heard no difference in my signal strength even with the 8 to 1 VSWR.
>
> I have an Imax 2000 that I use for 15 and 10. This antenna always showed an increase in signal strength on those bands over the loop. Now the reverse is true. I hear signals on the loop that are buried in the noise on the Imax. In 1 short hour I worked Cuba, Belfast, Nurenburg, and California getting great signal reports from them all and seeing beautiful S meter readings from them.
>
> I cannot explain this effect with any kind of theory. I simply don't know antenna theory. But it happened. My friend cannot explain it either but he tried using open wire feeds 30 years ago and will not use anything else.

I have a similar antenna at 35 feet, except is it a 160 meter loop fed with 225 feet of 600 ohm feed line. I use a Dentron MT-3000A antenna tuner with a built-in balun.

I tune the tuner using a MFJ 259B and get almost 1-1 SWR on all bands through 6 meters. On some bands and at some frequencies, the tuning is very narrow band. Particularly on 75 meters. If you are not using something like an antenna analyzer, you may be missing the correct spot for a 1-1 SWR.

Also, I always have to adjust the tuning for moisture, even here in the desert. Rain, ice and snow have a big effect.

The other side of the picture is the antenna really loves thunder storms and precipitation static. I have a big DPDT switch to open the feed line to the tuner and ground it directly. sometimes 1/4" arcs! You probably have already discovered this!

I love my loop! Even work 6 meter E's and contests with it.

73, Paul, KD7HB

Hi Jeff

Ok, very good points... this design may need better tools I have in hands for the stress checks...

But some numbers... 14MHz tapered element half, symmetric segments, starting at center 47" (OD 1", ID 0.625"), 24" (OD 0.875",ID 0.619"), 44" (OD 0.75", ID 0.619"),36"(OD 0.625",ID 0.467") and tip 58.7" (OD 0.5", ID 0.494") AL 6082, element wall dimensions are somewhat on a heavy side at the center segments... so is the weight a little...
Center gap 2" between element halves.

Currently planned support plate dimensions L 15.75" x W 7.87" thickness 0.393" FR4, element clamp positions 2" and 6.88" symmetric along plate long side, so two clamps for each element half, plate located above element for partial rain cover... Plate max size 19.6" x 9.8"...
Not yet processed, so no worries for changes...

Much appreciated if you have some dimensioning help for the center insulator diameter and length (minimum) handling the stress...

I may still need to consider FR4 bar covered with shrink tube, but ceramics are also on a map... but depending on support plate strength and bending at gap center (or between nearest clamps 2" off the gap center) there might be chance to forget whole center bar in the gap...

tnx oh6io

>>

Hi

Yes, thanks for good material analysis. It was really very odd to find this kind of failure *can* occur as gap was large and the material was good quality. Visually by eye there wasn't anything unusual in the gap inner surface, maybe they had been visible by more accurate means. But aging exists in all materials and other environments than dry and clean air shorten time for problems.
Insulator structure must taken account too...
Now to avoid similar troubles takes some more planning, the next insulator is smaller in diameter and element mechanical stress is also much lower...

tnx oh6io

im baffled by all this.its not my natural subject.This is what i want ta know- Some yrs ago i found the answrs in a usa book issued during WW2 for service people.It was in a combined volume and in individual ones like AC theory/etc.I made notes but now cant find books or notes as ill. The books explained all about how a wire or rod has, along its length things like capacitance/inductance/resistance and how shortening the wire or lengthening it caused changes in the effects.For instance on a full length dipole the ceter feed would be at max amps and lowest volts.etc.I can get this far but how the wire becomes capacative or inductive along its length i cant figure.For weeks ive drawn dozens of sine waves on scraps paper but stiil cant figure it.Ive tried internet but the advisors all seem to assume the reader is a genius. One writer has a book on here 70 pp long and goes into every technicality but,does not explain what i want to know.WHY.Ive tried using a resistance meauring noise bridge that folks claim is dead simple but i cant even understan what the resultant measurements indicate.The bridge dont measure inductance and,even if it did it would be of little use as in would not understand it.The clown who claim its simple the seem to write articles of baffling complexity so what world are they living in,not mine.I think the books earlier ref to have a name inside like kroger or similar.I wish i could find them.Why why why are books in uk impossible to understand compared with usa stuff like this or for instance early tab books which i cant find either.Looking forward to my next life as.could not be worse.Any ideas???Sure what i want to know is vital as a first principle so why this avoidance.

Its all to do with resonance. On either side of that the wire or antenna element becomes either inductive or capacitive. This quantity is usually called reactance (J) and dissipates no power.

> i cant figure.For
> weeks ive drawn dozens of sine waves on scraps paper but stiil cant

> claim is dead simple

A noise bridge is basically a comparator. It essentially compares a known quantity with an un-known one. When the bridge is balanced the known and un-known are equal in value. A calibrated capacitor should indicate which direction any reactance lays.

Grab one of the "Radio Handbooks" ! All the answers are in those.

If is any help one of the first books that I ever had was a copy of
"M.G.Scrogie" "Foundations of Wireless"
<https://en.wikipedia.org/wiki/M._G._Scroggie>

HTH.

It's easy to understand once one understands phasor (vector) math and the b=
asics of wave reflection. For a dipole, just remember that the current reve=
rses phase at the end of the element and the voltage doesn't. A dipole is a=
 standing wave antenna, i.e. there are forward waves and reflected waves on=
 each element. The feedpoint impedance of a dipole is (Vfor+Vref)/(Ifor+Ire=
f), all phasor math. A resonant 1/2WL dipole has two elements, each 90 degr=
ees long. If we pick the phase angle of Vfor as zero degrees for a referenc=
e, the reflected voltage will have traveled 180 degrees during its round tr=
ip and will therefore be 180 degrees out of phase with the forward voltage.=
 Phasors that are 180 degrees out of phase with each other simply subtract =
so the voltage at the feedpoint of a 1/2WL resonant dipole is |Vfor|-|Vref|=
, using regular math. The reflected current will have traveled the same 180=
 degrees plus another 180 degree phase shift at the end of the element. Tha=
t puts Ifor in phase with Iref so these two quantities simply add. Total fe=
edpoint current =3D |Ifor|+|Iref|. So the resonant feedpoint impedance of a=
 resonant 1/2WL dipole is:

Zfp =3D |Vfor-Vref|/|Ifor+Iref| =3D ~50-75 ohms at zero degrees, e.g. 50+j0=
 ohms

You say you understand why the resonant feedpoint is resistive so - so far =
so good? That part is relatively easy because the phase angle of the feedpo=
int impedance at resonance is zero degrees.

For a dipole that is shorter or longer than resonant, we have to use phasor=
 math because the phase angles are something other than zero and 180 degree=
s.

For a dipole a little shorter than resonant: Vfor+Vref will have a negative=
 phase angle. Ifor+Iref will have a positive phase angle. Zfp=3D(Vfor+Vref)=
/(Ifor+Iref) will have a negative phase angle, e.g. 100 ohms at -30 degrees=
, so the feedpoint impedance will exhibit capacitive reactance.

For a dipole a little longer than resonant: Vfor+Vref will have a positive =
phase angle. Ifor+Iref will have a negative phase angle. Zfp=3D(Vfor+Vref)/=
(Ifor+Iref) will have a potitive phase angle, e.g. 100 ohms at +30 degrees,=
 so the feedpoint impedance will exhibit inductive reactance.

When the dipole gets to one wavelength long, the voltages and currents are =
once again in phase or 180 degrees out of phase and the feedpoint impedance=
 becomes purely resistive once again. However, the extra 180 degrees in the=
 reflected wave's round trip results in in-phase voltages and out-of-phase =
currents.

For 1WL dipole: Zfp =3D |Vfor+Vref|/|Ifor-Iref|, i.e. a very high resistive=
 impedance, e.g. 5000+j0 ohms.

In the above posting, I mistakenly omitted some absolute value marks. For
instance, the above 1/2WL resonant equation should have been:

Zfp = (|Vfor|-|Vref|)/(|Ifor|+|Iref|)

I apologize for that boo-boo.

Yeah, you apologize and that's good, because he asked for basic basics
and you respond with vector algebra.

Seems you and I have a different definition for the word "basic". It is imp=
ossible to have a *BASIC* understanding of feedpoint impedance in standing =
wave antennas without having a *BASIC* understanding of phasor/vector algeb=
ra and a *BASIC* understanding of reflected wave theory. The great majority=
 of hams do not understand those *BASICS* and that is the reason for their =
confusion. I do not understand the *BASICS* of modern automobile mechanics.=
 That's why I take my vehicles to a dealership.

> He should add that the antenna with the reflected waves do not radiate.

:) The reflected waves, for a standing-wave antenna, are *on the antenna el=
ements*, NOT on the feedline. A resonate 1/2WL dipole has an SWR of ~20:1 o=
n the dipole elements. Reflected waves on a standing wave antenna radiate j=
ust as well as forward waves on a standing wave antenna. Both forward waves=
 and reflected waves on a standing wave antenna are common-mode and they ra=
diate equally well.

Here's a brain teaser for all. Assume a resonant 1/2WL dipole made from #14=
 wire at a height of 30 ft. Given: The characteristic impedance, Z0, of a #=
14 horizontal wire at a height of 30 ft. is calculated to be 600 ohms. The =
forward voltage on the dipole elements at the feedpoint is 100 volts. The f=
eedpoint impedance of the dipole is 50 ohms.

What is the reflected voltage at the feedpoint? What are the forward curren=
t and reflected current at the feedpoint? What is the SWR on the antenna el=
ements? What is the voltage at the tip ends of the dipole elements?

Anyone with a *BASIC* understanding of standing wave antennas will be able =
```

to answer those questions.

Ok, so a friend of mine died, and at his SK auction, I picked up about 6 antenna's for about $10 each.

Some were good and some were not so good...

I have a real friend who repairs my computer for free and he is into the CB radio.
I cannot get him to study and get his amateur radio license and I wanted

to get him involved in some type of radio - with the hopes that when he see's how much the CB radio sucks - he would want to study and take the test and get his license and quit fooling around with the CB radio...

His best friend drives truck for the DOT and is a garbage man on the side.
They had boxes of old CB radios, and I found a couple that still put out about 3 watts AM with good modulation.

The person my friend bought his computer shop from was an Amateur Radio Operator. He gave the guy a 48' piece of RG-8 coax and 30' of tower. The tower was bent and no one wanted it - even though it was not rusted or damaged in any other way.

So to help him out, I gave him the Ringo Ranger so he would at least have an outdoors antenna to play with.

I know a Ringo Ranger is a dummy load - no one has to explain it to me. But at my house with 120' of Belden 9913F7 - up about 28' off the ground, with ground radials, I was able to compare it to my Solorcon A99 - which is tuned for 10 meters.

The Ringo was about 1 or 2 S units less noisy and I was able to talk on 10 meters to a fellow in the Neatherlands with no problems.

So I gave him the antenna, told him to wait until I got there to help put it together and tune it.
When I got there, he already had it on top of the tower and was playing with it.
The VSWR read 5:1 on channel 19

We tried changing the strap match on the ring and it got down to about 3:1 after we changed the match and the length a couple of times.

So after a hearty supper - 4 hours after starting this fiasco, we took it down, put it on a piece of pipe out in the yard.
Took a second Ringo Ranger and combined the two - to make it 11'6 long.

Origionally it was around 9'

I got the match down flat to about 2:1 everywhere from channel 1 to 40!

That is as low as it would go.

I checked the coax and there was no shorts and I used a coax calculator and even with a .66 velocity factor - the brand and type is unknown - and I didn't have a working computer at the site - the length for a piece of coax in multiples of half wavelengths would only be somewhere in the neighborhood of being 2 feet less then what the coax is. Which isn't a big deal, except that he plans on adding another 20' of tower, sometime in the future.

I could give him my old Solorcon A99 and put up my new Solorcon A99 -

but I am afraid that if I give away my good antenna, I might have some problems with the Solorcon...

I do not have an antenna analyzer - but I could borrow one..
Yesterday was an exception - because it was a holiday and no one was around to ask if I could borrow theirs.

I know the Ringo needs ground radials and I am working on doing that for him also.
But I am wondering - if there might be another solution to the problem...

I think 11'6 is somewhere around .33 of one wavelength on channel 19....

I usually don't ask these kinds of questions - because usually I have the answer...

If a person had more then 3 watts - loosing half of it between the coax and the antenna mis match wouldn't be a problem...

As it is - he doesn't have a working home phone and I can't call him and he doesn't have internet so I can't email him and there is a hill between his place and my place - about 7 miles away - max and I can't hear him....

His mobile also has a 3:1 mismatch and he put a 104 inch whip on it and is able to talk about half way between his house and my house with his mobile - on the side of a jeep about 3' off the ground...

I have a legal 4 watt CB radio - which normally talks about 12 miles in all directions.

I am looking for idea's on how to make the Ringo better - if that is possible.

Maybe possible lengths to try - only I am afraid that if it gets too long - it will fall apart. The base is already wobbly from taking it up and down the tower 25 times last night.

I don't know if there is a way to tighten the base to the first section of antenna.

I would be willing to try to make it 18' long if that would be an improvement.

Any idea's?

To be blunt with you, Get the instructions for it. The thing is suspose to
be about 18 feet long. Not 9 feet or 11 feet 6 inches.

Go away SB, you are just wrong.  And this guy does not need wrong.

John, do not listen to this twit, he will only confuse you more as he
thinks 200 year old theories are correct when they are not.

Hello Rob.

Well, I'm thinking that where there is one then there will probably be
others. Perhaps the postings by Szczepan deter other Poles from posting.
73, Ian.

Good morning.

Nice try, but I'll let someone else play the game with you while I watch.

Wayne
W5GIE

But even I am not the poster. I only "copy and paste".

So the real posters are: Faraday, Lorenz, Tesla and Dirac.

They are using the words "oscillations" and "vibrations".
Wayne used the "leaping". It is also not precise.

In the antenna are the unsymmetrical oscillations like in the water waves:

Hello Szczepan.

Actually, yes, you are the poster. You copy and paste and post. The problem
is that you often don't understand the meaning / import of the text which

you are copying and pasting and posting nor do you learn from the postings
made in reply to you.

Regards, Ian.

Nope, just a Polish idiot pasting quotes history has proven wrong.

> They are using the words "oscillations" and "vibrations".

They died a long time ago; those words are not used now.

Makes me think back to an old joke from EE at college involving Poles, zeros and the right half of the (air)plane.

And I am Polish so I can make fun of my heritage. Our last name was quite different when my grandfather moved to the US.

```

So we have the three teams of posters:
1. Faraday, Stokes, Lorenz, Marconi, Tesla and Dirac,
2. Heaviside and Poynting,
3. You, Tom, Rob and Jimp.

From whom should I learn?

Do you know:
""Poynting and the Nobel prizewinner J. J. Thomson co-authored a
multi-volume
undergraduate physics textbook, which was in print for about 50 years and
was in widespread use during the first third of the 20th century.[5]
Poynting wrote most of it.[6""

For example in the textbooks the water waves are "transversal" and the space
is empty.
In the above link you can see that the water waves are longitudinal.
Have the stars the atmosphere?

Hello Szczepan. Teams 1 and 2 do not exist, do they? Faraday and the others
aren't sitting at computers and making posts, are they?
You're making posts with text that you seem not to understand. This confuses
you even more and amuses us.

Regards, Ian.

Yeah, so what?

> For example in the textbooks the water waves are "transversal" and the space
> is empty.

Gibberish.

> In the above link you can see that the water waves are longitudinal.

So what?

This is an antenna group not a boating group.

> Have the stars the atmosphere?

Irrelevant to anything.

Do you wear slip on shoes?

Do you agree with Heaviside and Poynting. Father of the famous vector wrote
in 1884 (before the Hertz experiment):

""Energy is transferred through empty space outside the wires".
"The whole of the energy then enters in through the external surface of the
wire, and by the general theorem the amount entering in must just account
for the heat developed owing to the resistance,"

As you should see the energy from the transmitter enters in through the
external surface of the
wire (antenna) and next is radiated as the heat.

It amuses me. And what about you?
Do you know that antennas radiate very,very lower frequences than heat?

"'How does energy really flow in electric circuits?'. The answer is fairly
standard university-level physics but is rarely mentioned in secondary
school text books".

What textbooks you have?

> "'How does energy really flow in electric circuits?'.

The coherent RF energy flows near the surface of the conductor at the speed=
 of light in clouds of photons. Given the magnitude of the Poynting vector,=
 we can calculate the number of photons passing through that area in unit t=
ime. Those coherent photons that extend into the inner surface effect area =
have the highest probability of their energy being converted into infrared =
higher energy photons, i.e. heat radiation. After all, RF photons cannot ex=
ist for long deep inside a real-world conductor and they cannot exist at al=
l inside a zero resistance conductor. Here's a question for you: How many 1=
0 MHz photons does it take to generate one infrared photon?

Only steady-state DC doesn't involve photons. All AC, RF, and transient DC =
functions involve photons and that has been accepted as scientific fact for=
 about a century. Unfortunately, the physicists being quoted by you were co=
mpletely ignorant of the existence of photons.

Hello Szczepan.
I am a licensed radio amateur and I am concerned with matching my aerial to
my transceiver. I'm personally not at all concerned about any heating
effect, theoretical or actual. Sounds like a topic for one of the physics
newsgroups.
As for textbooks, I have a shelf of them. You'll remember the
recommendations I made in other posts.
Regards, Ian.

Nope; proved incorrect or incomplete, depending on how you want to look
at it.

> As you should see the energy from the transmitter enters in through the
> external surface of the
> wire (antenna) and next is radiated as the heat.

Nope, not a chance.

> It amuses me. And what about you?

Your babbling?

Yes, it is amusing how you are always wrong.

> Do you know that antennas radiate very,very lower frequences than heat?

If by "heat" you mean infrared, then yes, standard radio frequencies are much lower than the frequency of infrared light, but you only got that correct by accident.

> "'How does energy really flow in electric circuits?'. The answer is fairly
> standard university-level physics but is rarely mentioned in secondary
> school text books".

Of course not; lots of detail in every field is ommited at the secondary school level.

So what.

> What textbooks you have?

Lots; all university level and all read.

Do you wear slip on shoes?

In the secondary school level are electrons.
In university level are the all theories including "proved incorrect or incomplete".
Students should know all of them.

>
>> What textbooks you have?
>
> Lots; all university level and all read.

So try to pick up the theorirs which are "proved incorrect or incomplete".

The first should be Heaviside's and Poynting's.

I don't have time to look up a lot of quotes but you can Google them for yourself:
Albert Einstein, Niels Bohr, Erwin Schrodinger, Werner Heisenberg, Max Born,
Wolfgang Pauli, Richard Feynman, et. al.

Babbling gibberish.

A secondary school education provides an overview of a subject.

A university education provides the fine details of a subject.

>>
>>> What textbooks you have?
>>
>> Lots; all university level and all read.

More babbling gibberish.

A textbook will rarely mention obsoleted theories.

Do you wear slip on shoes?

Posting-Frequency: posted twice monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/
d7d337db35f23326

the rec.radio.amateur.moderated Moderation Team had decided to consider |
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. After a successful trial |
period (90 days, through early July 2009), we decided to adopt this |
change permanently. |

Approved rec.radio.amateur.* newsgroups are those that are currently listed in the latest version of the "List of Big Eight Newsgroups" which is crossposted monthly to news.announce.newgroups, news.groups, and news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those that have been created consistent with the suggestions in "So You Want to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either "radio.amateur" or "ham-radio" in their names, including uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved newsgroups up-to-date. In case we have overlooked any, and a submission is rejected in error as a result, the rejected submitter can E-mail us at our administrative contact address (in the signature at the bottom of this article, and the default Reply-To for the rejection message) requesting that it be added, and that the article be approved. We may still choose to reject articles crossposted to any alt.* newsgroup with an inappropriate name, including obscene language, embedded name-calling, or encouragement of unlawful conduct.

Please direct any comments, questions, or criticisms to rec-radio-amateur-moderated-request@panix.com.

Hi everyone:

I am about to compare the performance of two HF antennas and have an idea f=
or doing this, that I would appreciate comments on.

The objective is to determine which antenna yields a stronger signal to DX =
locations, and even get a measure of the difference in dB. I am assuming th=
at the antennas are reciprocal, so if antenna A receives an X-dB stronger s=
ignal than antenna B, antenna A will also yield an X-dB stronger signal fro=
m my transmitter to that location. So, I would like to measure the signal s=
trengths received through these antennas and compare them. For this I would=
 listen for CW or digital mode signals, switch back and forth between anten=
nas, turn off the AGC and record the audio into a file (or monitor it direc=
tly), where I could accurately estimate the signal strengths and compare. I=
 realize that different noise levels, fading, intermittent signal transmiss=
ion, etc. will affect the absolute signal levels, so the software should be=
 able to handle this. For example, by measuring the signal carrier alone an=
d/or SNR. And it would be nice if the software could give me an "envelope r=
eading" of the signal, for example, to estimate the CW signal.

Do any of you have comments on this methodology to compare antenna performa=
```

nce? And do you know of any DSP / sound card software that could be used f=
or this?

73 - Kristinn, TF3KX

Free, made for ham radio, and possibly better:
<http://www.qsl.net/dl4yhf/spectra1.html>
<http://www.weaksignals.com>

When using detected audio to compare antennas, make sure you're
comparing signals, not comparing noise levels. Picking up more
atmospheric noise is not the mark of a better antenna.

NO!

Actually, I have been in a hotel room with something similar. Well, the earth wasn't actually a cup of earth but the wires were coming out of the wall. Ah well, if you know they are wires then you'll also know to be very careful with them (especially in a damp bathroom). If you don't know they are wires then you'd probably not be in a hotel in the first place?

73, Ian.

Summary: Recruitment announcement for ham-radio-related FAQ articles

Keywords: FAQ, Intro, amateur, ham, radio, recruit, recruitment

Posted-By: auto-faq 3.3.2 beta (PGPMoose V2.0, Perl 5.005)
Archive-name: radio/ham-radio/recruitment
Revision: 1.2 2009/11/25 14:41:01
Posting-Frequency: posted twice monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been recently revived by an active moderation team. We are currently seeking suitable information, FAQ, and bulletin articles from the entire rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our newsgroup.

We are seeking a replacement maintainer for the following information bulletin formerly posted to rec.radio.amateur.* (and currently archived at http://www.faqs.org/faqs/radio/personal-intro/):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

One significant omission, requiring immediate updates, for this article |
is that it does not mention newer amateur radio newsgroups created since |
it was written, including: |

rec.radio.amateur.antenna |
rec.radio.amateur.boatanchors |
rec.radio.amateur.dx |
rec.radio.amateur.equipment |
rec.radio.amateur.homebrew |
rec.radio.amateur.moderated |
rec.radio.amateur.space |

We are willing to provide any technical support necessary to get this article updated and automatically posted again at a regular interval. This would include establishing contact with the original maintainer for any necessary permissions. We would prefer to seek a new, dedicated maintainer at this time, rather than start auto-posting the original article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to
rec-radio-info-request@panix.com.

resonant antenna [´res·ən·ənt an ´ten·ə]
(electromagnetism)
An antenna for which there is a sharp peak in the power radiated or intercepted by the antenna at a certain frequency, at which electric currents in the antenna form a standing-wave pattern.

McGraw-Hill Dictionary of Scientific & Technical Terms, 6E, Copyright © 2003 by The McGraw-Hill Companies, Inc.

I thought a resonant antenna was resistive without any reactance.

> I thought a resonant antenna was resistive without any reactance.

Consider a transmission line with standing waves. There is a point every 1/=
2WL where the impedance is a low "resistance without any reactance". That i=
s the point where the standing wave voltage is in phase with the standing w=
ave current. A 1/2WL dipole is a standing wave antenna with an SWR on the a=
ntenna of approximately 20:1. At the center feedpoint, the standing wave vo=
ltage is in phase with the standing wave current so the feedpoint impedance=
 is "resistive without any reactance".

If you look at the current and voltage distribution on a standing wave ante=
nna you will find that it looks just like the current and voltage distribut=
ion on a transmission line with reflections.

Hello, and resonance for an antenna (or any device for that matter) occurs when the reactive component of the input impedance vanishes. For a given impressed voltage, the input current is relatively large at resonance. The definition cited above is completely consistent with

this state (Did you really think something from a McGraw-Hill book
wouldn't be a "proper" definition?)

Now, we also have "antiresonance" in which the reactive component also vanishes but for a given impressed voltage the input current is relatively small.

Both resonance and antiresonance occur in antennas (but at different frequencies). Sincerely, and 73s from N4GGO,

The standing waves will exist whether resonant or not.

It is resistive *at the feedpoint* when properly made.

John

At 14.32 MHz a certain dipole accepts 159.2w from a 100v source into a reso=
nant 62.8 ohm feedpoint impedance. At 14.25 MHz, it accepts 160.2w from a 1=
00v source into a non-resonant 61.9-j6 ohm feedpoint impedance. So it appea=
rs that you are technically correct but maybe splitting hairs.:)

Seems that these conditions would also exist for any conjugately matched no=
n-resonant standing-wave antenna.

It does not say "a sharp peak in the power *accepted*" by the antenna.

EM was "correctly" described by Heaviside and Pointing in XIX century before
the Hertz experiment.

Not always. The "nonterminated transmission line" may be the Lodge's wire or
Your antenna (short dipole).
In your antenna the electrons are not reflected and do not destroy your
transmitter. They JUMP OFF Periodically = pressure waves.
Do not write that I claim it. It is the explanation by Faraday, Lorenz,
Tesla and Dirac. The all is in the each textbooks. But in different chapters
(lessons).
>
>> If yes, than you must admit that the leakage must be stronger at "recoil

In each textbooks is the Richardson equation. The electron field emission is
voltage and temperature dependent.

Do you understand the Pointing explanation that nothing if flowing in the conductor?

For me: " But then later it was found that the first (Pointing) discoveries were not entirely correctly described."

> Yes

Mechanically.
Also electrically?
>
>> It seems that one of them is a counterpoise.
>
> Why? I see symmetrical elements.

I see that the voltages are not symmetrical when the diode shines.
I bet that is the such orientation vs a oven that is the symmetry and no shine.
>
> What you can also see here is that this is another example of what

> the air.

From Maxwell's time all circuits are closed. So sometimes the current must flow in the air. Of course sometimes is enough if only part flows in the air. It is the leakage.
At HF the leakage is rather large.

Not in my antenna.
Not in your antenna either, because you have no antenna.

> Do not write that I claim it. It is the explanation by Faraday, Lorenz,
> Tesla and Dirac. The all is in the each textbooks. But in different chapters

Maxwell did not believe in current flowing "in the air". That's why he used=
 the concept of "displacement current". He was ignorant of photon energy fl=
ow being the equivalent of current flow. Nowadays, we know that when it app=
ears that coherent current is flowing in the air or indeed through any diel=
ectric (including free space), it is actually photons that are doing the fl=
owing, i.e. photons are accomplishing the energy transfer *as if* current w=
ere flowing through charge carriers. All EM field/wave phenomena involve qu=
antized photons.

For those who still believe in displacement current, it is easy to prove th=
at, under certain conditions, the displacement current would have to violat=
e the speed of light limit in order to accomplish the energy transfer in th=
e measured time.

> Do you understand the Pointing explanation that nothing if flowing in=20
> the conductor?

Quoting "Fields and Waves ...", by Ramo & Whinnery: "A perfect conductor is=
 usually understood to be a material in which there is no electric field at=
 any frequency. Maxwell's equations ensure that there is then also no time-=
varying magnetic field in the perfect conductor."

In the non-perfect real world, something is flowing in the skin effect dept=
h of a conductor which is the cause of the power losses in the conductor.

The whole XX century was the century of intensive egzamination/explanation
of the field electron emmission.

If not in your antenna than you should be able to explain what the electrons
do in your antenna if they are not reflected (VSWR = 1).
Do you try?

> (maybe this evening they will, thunderstorms announced. but not because
> of transmissions)

Your antenna goes into receiving.
But I do not know if the electrons are injected into your antenna.
Are they?

I hope not! I don't like electrons injected in my antenna.
It is very costly because of all the damaged equipment.

Why you do not like the electrons?
For what you need the next " the equivalent of current flow".

Babble; Jefimenko's equations describe how antennas work and there are
no jumping electrons involved.

>>> Do not write that I claim it. It is the explanation by Faraday, Lorenz,

No, it was the century of examination of elecromagnetic radiation; antennas
have nothing to do with field electron emmission as field electron emmission
is a result of electrostatic fields and antennas work on electromagnetic
radiation.

> If not in your antenna than you should be able to explain what the electrons
> do in your antenna if they are not reflected (VSWR = 1).

The electron in any antenna flow back and forth between the antenna terminal.
```

There are no electrons either jumping off of or onto an antenna.

This is a figment of your imagination.

VSWR has nothing to do with electrons and everything to do with
elecromagnetic fields.

> Do you try?

Try what?

>

> But I do not know if the electrons are injected into your antenna.

Electrons may be injected into an antenna by a lighning strike, but that
has nothing to do with how antennas work.

> Are they?

No, not other than by a lighning strike.

```

> But today we know that this is not true.

"A great deal of analytical and experimental work has been done over the
past 100 years on the design and performance of ground systems for
verticals. "
And in summary: "Depending on the character of the soil, it is possible
there may be some increase in soil conductivity as we go up in frequency
which might compensate a bit. "

"The purpose of the radial system is to divert current from the soil into
the radial conductors which have very low loss compared to soil. We can
calculate the current division between a radial system and the soil ".From:
http://www.kkn.net/dayton2004/HF_vertical_ground_system_design_N6LF_Dayton.pdf

For me the current between the radial and soil (or air) is the leakage:

Is at HF the leakage rather large?

S*.

In vacuum they flow without sparks. They flow at low voltages (10V) and the
cold cathode. In air is the same.
Do you like such?

Nope, you have no clue what is actually happening.

> Is at HF the leakage  rather large?

This is a nonsense question based on a total lack of understading of
what is really happening.

> Why you do not like the electrons?

I don't dislike electrons and have a bunch of them in my body. Without free=
 electrons, antennas wouldn't be able to radiate photons.
=20
> For what you need the next " the equivalent of current flow".

Technically, current is defined as the movement of charged particles. Since=
 photons don't carry an electric charge, they technically don't meet the de=
finition. But since current flow implies energy transfer and photons are ca=
pable of energy transfer, one can come up with the concept of "equivalent c=
urrent" corresponding to photon movement. Thus the "current flow" through a=
 capacitor is explained by photon flow rather than displacement current.

My antenna is not in vacuum.  I don't like to see or hear the effects
of sparks or other discharges from my antenna.

> Are the voltages doubled at the ends?

The voltage doubling at the ends of a dipole is simple to understand. A dip=
ole is a standing wave antenna. When the forward wave from the feedpoint en=
counters the open-circuit at the end of the dipole wire, a reflection takes=
 place where the reflected voltage is in phase with the forward voltage and=
 the reflected current is 180 degrees out of phase with the forward current=
.

At the end of the dipole, |Vfor|=3D|Vref| and |Ifor|=3D|Iref|. So the total=
 voltage and total current at the ends of a dipole are:

Vtot =3D Vfor + Vref =3D 2*Vfor =3D 2*Vref

Itot =3D Ifor - Iref =3D 0

And of course, no current is going to flow into the open-circuit at the end=
 of the dipole so the total energy in the magnetic field at that point is z=
ero.=20

All of the energy in the EM waves migrates to the electric field and that's=
 why we get a standing wave voltage maximum at the ends of a 1/2WL dipole.

However, under certain corona conditions, when the impedance at the end of =
the dipole conductor is much less than infinite, electrons actually migrate=
 from the antenna into the conductive air, e.g. salty fog on the coast. But=
 this is undesirable non-coherent behavior unless you are building a Tesla =
coil.

I once saw a mobile antenna emitting a red corona glow in the fog on HWY 1 =
near Monterrey, CA. A traffic cop stopped him for having a "red light" that=
 could be seen by oncoming traffic.:)

Not all antennas have ends so your question is basically meaningless.

For those antennas that do have ends, the voltage and current distribution
depends on the length of the antenna in terms of wavelengths and can be
anything.

"Energy transfer": "Umov was the first who introduced in physics such basic
concepts as speed and direction of movement of energy,".
" In his first works of this period, Umov considered potential energy as
kinetic energy of some environments "imperceptible for us"."
From: http://en.wikipedia.org/wiki/Nikolay_Umov

Photons as the wave packet transfer the energy in the same way as the sound
waves.
In radars are "pulses". Light is not coherent. It consists of pulses or
photons. The same is in sonars.

For what you need the new "photons".

Good morning Szczepan.
Sound waves propagation through a gaseous medium. No medium - no sound wave.

Light waves and radio waves can propagate without a gaseous medium.
Please get a textbook and read some theory. If you choose to say, once
again, that textbooks are for children then do remember that children can
learn and understand.

Regards, Ian.

Exactly like with the sound waves.

You assume that there no field electron emission. Why?

>All of the energy in the EM waves migrates to the electric field and that's
>why we get a standing wave voltage maximum at the ends of a 1/2WL dipole.

Nobody know what the EM waves are. Write about electrons.

>However, under certain corona conditions, when the impedance at the end of

They migrate if the voltage is:
"Field emission was explained by quantum tunneling of electrons in the late 1920s. This was one of the triumphs of the nascent quantum mechanics. The theory of field emission from bulk metals was proposed by Ralph H. Fowler and Lothar Wolfgang Nordheim.[1] A family of approximate equations, "Fowler-Nordheim equations", is named after them."

>I once saw a mobile antenna emitting a red corona glow in the fog on HWY 1
>near Monterrey, CA. A traffic cop stopped him for having a "red light" that
>could be seen by oncoming traffic.:)

Each your antennas are the electron emitter:
"How would the ideal field emitter look like? It should be very long and very thin, made of conductive material with high mechanical strength, be robust, and cheap and easy to process". From:
http://ipn2.epfl.ch/CHBU/NTfieldemission1.htm

The voltage doubling is only theoretical. In reality the voltage is rising to the level necessary for effective field emissions.
If no proper voltage no radiation.
S*

Because if it was there, you would see the sparks and corona effects.

> Each your antennas are the electron emitter:

Of course we all know that antennas exist that are not long and thin,
and still work very well.  Well, we all know that except you the stubborn
Pole.

> You assume that there no field electron emission. Why?

Please don't tell me what I am assuming because you are invariably wrong. A=
s I (and Richard Feynman) have told you before, the fields emitted by elect=
rons consist of photons. Electrons escaping a transmitting antenna are a no=
n-coherent corona discharge. Photons escaping a transmitting antenna are co=
herent RF energy.

Back in the early 20th century when spark gap transmitters were being used,=
 the spark gap function, like lightning, generated non-coherent photons whi=
ch filled the RF spectrum. Nowadays, a CW signal is mostly coherent with a =
small amount of non-coherence associated with the transient rise and fall t=
imes.

> Light is not coherent.

On the contrary, any single frequency light, i.e. single color light, is coherent.

Most of the laser light in an interferometer is coherent. Otherwise, steady-state interference could not be achieved.

Have you the result of counting of electrons which go forwards and backwards
at the feed point?

You have the misunderstanding that the current on the outside of the coax cable is the result of electron emission by the antenna. This is of course not true. It is the result of imperfect symmetry or imperfect balun operation.

"Electric currents that oscillate at radio frequencies have special
properties not shared by direct current or alternating current of lower
frequencies. The energy in an RF current can radiate off a conductor into
space as electromagnetic waves (radio waves); this is the basis of radio
technology."

As you see something radiate off a conductor into space. So the something
must be in the space.
Are such issue (special properties) for children?

But now is possible to measure the currents. Somebody wrote: "I'm a big fan
of RF current meters".
Do you know the results?

All natural sources produce the damped waves. They are not coherent at all
frequences.
Only today radio transmitter and free electron laser are able to produce
undamped waves.

It were the damped waves.
http://en.wikipedia.org/wiki/File:Ondes_amorties.jpg
For Planck and Einstein that wave packets were the portion of energy. The name photon have many definitions.

> Nowadays, a CW signal is mostly coherent with a small amount of

Are in CW a photons?

Because there isn't any because field electron emission is caused by
an electrostatic field and antennas have electromagnetic fields.

You have been told this several times; why do you continue to ask the
stupid question?

>>All of the energy in the EM waves migrates to the electric field and that's
>>why we get a standing wave voltage maximum at the ends of a 1/2WL dipole.

> Nobody know what the EM waves are. Write about electrons.

Everybody reading the news group except you knows what EM waves are.

Electrons have nothing to do with a propagating EM wave.

You have been told this several times; why do you continue to make this
stupid statement?

>>However, under certain corona conditions, when the impedance at the end of

The theory of field emission from bulk metals was proposed by Ralph H. Fowler and Lothar Wolfgang Nordheim.[1] A family of approximate equations, "Fowler-Nordheim equations", is named after them."

This has nothing to do with antennas because field electron emission is caused by an electrostatic field and antennas have electromagnetic fields.

>>I once saw a mobile antenna emitting a red corona glow in the fog on HWY 1 near Monterrey, CA. A traffic cop stopped him for having a "red light" that could be seen by oncoming traffic.:)
>
> Each your antennas are the electron emitter:

No, they are not.

> http://ipn2.epfl.ch/CHBU/NTfieldemission1.htm

Not all antennas are either long or thin; loop antennas work just fine.

> The voltage doubling is only theoretical. In reality the voltage is rising to the level necessary for effective field emissions.
> If no proper voltage no radiation.

This pure, babbling, nonsense.

You are an ignorant, babbling, ineducable idiot who knows absolutely NOTHING about how anything works.

You don't even understand what an antenna is or the difference between an electric field, a magnetic field, and an electromagnetic field.

Electrostatic and magnetostatic fields are created by DC.

An antenna is a device that converts the AC electrical energy at its teminals into electromagnetic energy which radiates from the antenna and also coverts the electromagnetic energy which antenna intercepts into AC electrical energy at it's terminals.

That is ELECTROMAGNETIC energy, not magnetostatic nor electrostatic energy.

How many antennas have you built in your lifetime?

Why do you refuse to answer the question?

Is it because you have built zero antennas and you are trying to say all the people that have successfully built hundreds that they are all wrong and you don't want to admit you are an ignorant, inducable, idiot?

Why can't you obtain and read a university level textbook on anything in
any language?

Is it because you are too stupid to be able to understand the material?

And he was essentially wrong in the details as were most of the early physicists.

> Photons as the wave packet transfer the energy in the same way as the sound
> waves.

No, it is not.

> In radars are "pulses".

There is such a thing as CW radar which is not pulses, so you are wrong yet again.

> Light is not coherent.

Whether or not light is coherent depends on the source of the light; sunlight and candles are not coherent but lasars are coherent.

> It consists of pulses or
> photons.

A pulse and and photon are two entirely different things.

Light may or may not be pulsed, but it is always photons.

> The same is in sonars.

No, sonar is like radar only in very general terms.

> For what you need the new "photons".

For what you need a new brain because the one you have doesn't work.

You are an ignorant, babbling, ineducable idiot who knows absolutely NOTHING about how anything works.

Wrong, AC at ANY frequency can radiate off a conductor into space as
electromagnetic waves.

> As you see something radiate off a conductor into space. So the something
> must be in the space.
> Are such issue (special properties) for children?

None of that made any sense what so ever and was nothing but gibberish.

You are an ignorant, babbling, ineducable idiot who knows absolutely
NOTHING about how anything works.

You have no clue what the word "damped" means, do you?

The Sun, which is a natural source, does not produce damped waves.

Being damped and being coherent are two independant properties.

> Only today radio transmitter and free electron laser are able to produce
> undamped waves.

Wrong again because you have no clue what the word "damped" means; almost EVERYTHING produces undamped waves.

You are an ignorant, babbling, ineducable idiot who knows absolutely NOTHING about how anything works.

Why can't you obtain and read a university level textbook on anything in any language?

Is it because you are too stupid to be able to understand the material?

However, since you have no understanding of anything, you would be better to start with a grade school textbook as your knowledge is that of a five year old.

AC is in oscillating circuit (closed circuit). RF current is in an antenna
(open circuit).

Oh dear. Szczepan must realise that what he's written is nonsense. He's deliberately writing it to have a laugh, isn't he (and that's a statement, not a question). I think he's gone a bit far with at one.

Regards, Ian

Wrong again, moron.

AC means Alternating Current as opposed to DC or Direct Current.

RF means Radio Frequency and is generally used to the AC that is being
received by a receiver or transmitted by a transmitter.

None of these terms has anything to do with open or closed circuits.

You are an ignorant, babbling, ineducable idiot who knows absolutely
NOTHING about how anything works.

As a matter of fact, if one builds a 1/2WL dipole for 60 Hz (~1553 miles long), it will obey the same laws of physics that a 1/2WL dipole at 60 MHz does.

Yes. But RF CURRENT is: " "Electric currents that oscillate at radio
frequencies have special
>> properties not shared by direct current or alternating current of lower
>> frequencies. The energy in an RF current can radiate off a conductor into
>> space as electromagnetic waves (radio waves); this is the basis of radio
>> technology."

Now are also ULF transmitters (30Hz). So the above is not precise.
What decide that "an RF current can radiate off a conductor into space"?

Where ever you got this piece of trash quote, it is wrong just like all
your ancient quotes from over a hundred years ago.

AC of any frequency can radiate off a conductor into space as
electromagnetic waves.

> Now are also ULF transmitters (30Hz). So the above is not precise.
> What decide that "an RF current can radiate off a conductor into  space"?

That the AC is applied to an appropriate antenna.

That is the purpose of an antenna, to convert AC into electromagnetic waves.

For the third time, AC of any frequency can radiate off a conductor into
space as electromagnetic waves.

There is no minimum frequency.

Hello Szczepan.
"> The condenser also radiate? "
Try asking on sci.physics.electromag. If the diagram is trying to equate a
capacitor to an antenna then I'd not agree with that at all.
"> What the appropriate antenna looks like?"
It would be an antenna that matches to the transmitter. You wouldn't use an
antenna that is a mismatch as this would defeat the purpose of the antenna.
"> Is an antenna the open circuit?"
From my viewpoint it is not. "Open circuit" = "no current" and we know that
antennas carry a current.

Several postings have recommended that you acquire a textbook. I have a
suspicion that you already have one ....

Regards, Ian.

It is known from Hertz experiment. He used plates or balls.
Of course the plates are as on the diagram.

"Well, the antenna end, we have an Open Circuit - so the point with the
Highest Voltage"

No.

This depicts electorstatic fields; antennas radiate electromagnetic
fields, so your question makes no sense.

>>> Now are also ULF transmitters (30Hz). So the above is not precise.
>>> What decide that "an RF current can radiate off a conductor into  space"?
>>
>> That the AC is applied to an appropriate antenna.
>
> What the  appropriate antenna looks like?

It makes no difference what the antenna looks like as the only property
that matters is its ability to convert AC electrical energy at the input
frequency to electromagnetic radiation.
```

```
>> That is the purpose of an antenna, to convert AC into electromagnetic
>> waves.
>>
>> For the third time, AC of any frequency can radiate off a conductor into
>> space as electromagnetic waves.
>>
>> There is no minimum frequency.
>
> Is an antenna the open circuit?

No.

An antenna is a device that converts the AC electrical energy at its
teminals into electromagnetic energy which radiates from the antenna
and also coverts the electromagnetic energy which antenna intercepts
into AC electrical energy at it's terminals.

Do you wear slip on shoes?
```

I looked at one of the Hoperf parts and found this:

"The RFM69H is intended for applications over a wide frequency range,
including the 433 MHz and 868 MHz European
and the 902-928 MHz North American ISM bands."

That's the catch. Although it is capable of operating at 10dBm on 433,
you are responsible for only doing that in Europe where it is legal.
Otherwise, you may operate it at its maximum power capability here in
the US on 915MHz. Under those conditions, it complies with FCC regs.

No you were babbling about electrons jumping off the end of the antenna yet again.

You have also been told many times that the speed of the electrons in the conductor is less than a slow crawl.

How stupid are you that you are told these things time and again but you still can't understand them?

> After the diode is DC.
> Where electrons come from?

The electrons are always in the conductors and they stay in the conductors,
they don't "come" from anywhere.

You are an ignorant, babbling, ineducable idiot who knows absolutely
NOTHING about how anything works.

An antenna is a device that converts the AC electrical energy at it's
teminals into electromagnetic energy which radiates from the antenna
and also coverts the electromagnetic energy which antenna intercepts
into AC electrical energy at it's terminals.

How many antennas have you built in your lifetime?

Why do you refuse to answer the question?

Is it because you have built zero antennas and you are trying to say all
the people that have successfully built hundreds that they are all wrong
and you don't want to admit you are an ignorant, inducable, idiot?
```

Why can't you obtain and read a university level textbook on anything
in any language?

Is it because you are too stupid to be able to understand the material?

You are right:
"A simple rectenna element consists of a dipole antenna with a diode
connected across the dipole elements." And:
"A nantenna is a very small rectenna the size of a light wave, fabricated
using nanotechnology, which acts as an "antenna" for light,"

Each rectenna arm (or dipole element) must be shorter then 1/4 WL.

But: "Where the electrons come from?

You are an ignorant, babbling, ineducable idiot who knows absolutely
NOTHING about anything.

An antenna is a device that converts the AC electrical energy at it's
teminals into electromagnetic energy which radiates from the antenna
and also coverts the electromagnetic energy which antenna intercepts
into AC electrical energy at it's terminals.

Since an antenna is defined in terms of it's terminals, anything that
may be connected to the terminals, such as a balun, transmission line,
or diode has NOTHING to do with what the antenna is or how the antenna
operates.

What that also means is the current flows between the antenna terminals no
matter what type of antenna it is.

How many antennas have you built in your lifetime?

Why do you refuse to answer the question?

Is it because you have built zero antennas and you are trying to say all
the people that have successfully built hundreds that they are all wrong
and you don't want to admit you are an ignorant, inducable, idiot?

Why can't you obtain and read a university level textbook on anything
in any language?

Is it because you are too stupid to be able to understand the material?

Or you could use a ferrite antenna with a coupling coil wound to match the impedance.

Oh, wait, that would be a coil wound around a ferrite bar with no ground connection whatsoever and no place for jumping electrons.

Good Lord, could it possibly work with no jumping electrons and no ground?

> I'm pretty sure that some of the early radar receiving systems used
> essentially a dipole antenna feeding a crystal receiver.

Yes, some early microwave receivers were in essence crystal sets until the components became available to build the stages necessary for a superheterodyne receiver.

Most of the simple Gunn diode based door openers are also basically crystal set receivers.

Where do electrons jump from in a horn antenna?

Good afternoon Szczepan. I see that, after several weeks and lots of
postings, you still do not understand the difference between a monopole and
a dipole. Please also note the phrase "behaves as".
Kindest regards, Ian.

Oh, I am forever screwing up it's/its when I'm typing fast and not
particularly thinking about what I am writting; i.e. when responding to
Polish morons and spending as little time as possible on it.

The average speed.
The circuit with an antenna was named "open circuit" before Maxwell.
Maxwell discovered that the current is "prolongated" in the insulator
(displacement current) so the all circuits are "closed".
So at the bonduary the electrons must jump off. And come back.
In each textbooks is wrote that electrons jump off from a conductor and come
back.
But sometimes this phenomena is not symmetric.

"behaves as"means that radiate the same as the real dipole.

"I see that, after several weeks and lots of  postings, you still do not
understand the difference between the Hertz dipole and Marconi antenna."

Everything you just wrote is babbling, moronic, nonsense.

You are an ignorant, babbling, ineducable idiot who knows absolutely
NOTHING about how anything works.

How many antennas have you built in your lifetime?

Why do you refuse to answer the question?

Is it because you have built zero antennas and you are trying to say all
the people that have successfully built hundreds that they are all wrong
and you don't want to admit you are an ignorant, inducable, idiot?

Why can't you obtain and read a university level textbook on anything
in any language?

Is it because you are too stupid to be able to understand the material?

You are an ignorant, babbling, ineducable idiot who knows absolutely
NOTHING about anything.

You don't even understand what an antenna is or the difference between
an electric field, a magnetic field, and an electromagnetic field.

An antenna is a device that converts the AC electrical energy at it's
teminals into electromagnetic energy which radiates from the antenna
and also coverts the electromagnetic energy which antenna intercepts
into AC electrical energy at it's terminals.

Since an antenna is defined in terms of its geometry with respect to its terminals, anything that may be connected to the terminals, such as a balun, transmission line, or ground has NOTHING to do with what the antenna is or how the antenna operates.

How many antennas have you built in your lifetime?

Why do you refuse to answer the question?

Is it because you have built zero antennas and you are trying to say all the people that have successfully built hundreds that they are all wrong and you don't want to admit you are an ignorant, inducable, idiot?

Why can't you obtain and read a university level textbook on anything in any language?

Is it because you are too stupid to be able to understand the material?

The same as any other antenna; they are always in the conductor and don't "come" from anywhere.

The voltage developed at the antenna terminals causes the electrons in the conductors to move.

You are an ignorant, babbling, ineducable idiot who knows absolutely NOTHING about how anything works.

Hello Jimp. I still prefer to think of it as an electron doing its own
thing for independence.

Seems to me that most of the postings from Szczepan tend to be
copy-and-paste ones rather than "original thought" ones. I suspect he is an
old East European having a laugh at us Westerners but I wouldn't dispute the
other Ian's suggestion that we're dealing with a Turing test.

Is a moron akin to a proton?

73, Ian.

You are an ignorant, babbling, ineducable idiot who knows absolutely NOTHING about antennas or how they work.

You don't even understand what an antenna is or the difference between an electric field, a magnetic field, and an electromagnetic field.

Electrostatic and magnetostatic fields are created by DC.

An antenna is a device that converts the AC electrical energy at it's teminals into electromagnetic energy which radiates from the antenna and also coverts the electromagnetic energy which antenna intercepts into AC electrical energy at it's terminals.

That is ELECTROMAGNETIC energy, not magnetostatic nor electrostatic energy.

From http://en.wikipedia.org/wiki/Biot%E2%80%93Savart_law

"The Biot-Savart law is fundamental to magnetostatics, playing a similar role to Coulomb's law in electrostatics. When magnetostatics does not apply, the Biot-Savart law should be replaced by Jefimenko's equations."

What that means, you babbling idiot, is that Jefimenko's equations apply to antennas, not the Biot-Savart law or Coulomb's law.

Jefimenko's equations were first published in the 1960's so anything written before then is essentially irrelevant to a discussion of antennas.

How many antennas have you built in your lifetime?

Why do you refuse to answer the question?

Is it because you have built zero antennas and you are trying to say all
the people that have successfully built hundreds that they are all wrong
and you don't want to admit you are an ignorant, inducable, idiot?

Why can't you obtain and read a university level textbook on anything
in any language?

Is it because you are too stupid to be able to understand the material?

I'll try, but I'm a bit busy with work right now.  I'll get back to
this in the next day or two, and when I get some replies to several
emails.

One of these?
<http://www.alibaba.com/product-gs/310363481/315_433Mhz_wireless_pager_system_for.html>
<http://www.alibaba.com/product-gs/541027413/Wireless_service_calling_system_for_restaurant.html>
<http://www.alibaba.com/product-gs/496387830/Restaurant_paging_system_table_button_with.html>
<http://factory.dhgate.com/pos-terminal-cash-register/433mhz-restaurant-ordering-terminal/-wireless-restaurant-ordering-device/-wireless-ordering-device-p39229505.html>
<http://www.aclas.tw/Products/Application-Restaurant/Restaurants-ordering-system.html>
<http://www.aclas.tw/PDF/Restaurants-Ordering-System.pdf>
etc... ALL (and I do mean all) of the ones listed under "wireless
order system restaurant" on Alibaba run on 315 - 433MHz.

Remind me to lookup the rules for 433MHz in China.

>from the sound of the transmissions

Lovely. Remind me to rant on the topic of wireless systems that belch
RF when there's no data to transfer.

>I got a look at one of the handheld terminals, and did not see any
>sort of FCC licensing or type-acceptance sticker.

Here's the FCC interference complaint form:

<https://esupport.fcc.gov/ccmsforms/form2000.action?form_type=2000F>
It's an election year, so the FCC EB may actually be interested in doing something. At the least, the restaurant owner will get a warning letter in the mail.

```

You still have not explained how it is possible that the behaviour
is not symmetric and still there is no nonlinearity in the antenna.

Continuing the investigation, I find that the US has no ISM band
anywhere near 433MHz. The closest is 915MHz.

Interestingly, on that band, the FCC says:

"� 18.305 Field strength limits.

(a) ISM equipment operating on a fre-
quency specified in � 18.301 is permitted
unlimited radiated energy in the band
specified for that frequency."

Wow! Unlimited!

The catch is that you may have no emissions outside the ISM bands exceeding 25uV/m at 300m. That would be equivalent of less than 2 microwatts of 2nd, 3rd,.... etc, harmonics and other stuff being radiated by the antenna. That, I think, would be about -37dBc when running 10mW. The more power you run, the harder it gets to filter.

In addition, I still have some questions in my mind about certification. Just because a manufacturer says it will meet the requirements, doesn't necessarily mean it is certificated. Part 15 (not ISM) allows us to build our own transmitters which are not for sale. But, I can find no mention of that in part 18 (ISM).

Still lots of questions out there.

May the group forgive me for what I am about to post....

Your admission that you know "he will never answer..." and your repeated and repetitious replies have drawn out the threads in which you both become involved to great lengths. This has done little to make you appear much different from him,
and, in my opinion, little to enhance your standing among those who have carried on intelligent discussions in the past. Isn't enough enough? Or are you just another troller as well?

As I've said before - "What a maroon!"

He don't get it. Or he's a troll.

It matters little, you all keep feeding him.

Stop.

tom

I had a crystal radio & the antenna was a piece of wire hanging out of it & the radio was built in a wooden box & I could listen to it on the second floor of a wooden building & sitting on a wooden chair. no connection to the ground (earth) as you say is required & the station I listened to was a daytime station located about 50 miles away...How did it work & no connection to the ground (earth) as you say is required & no battery power & the crystal had a cat wisker for tuning...

Ian wrote:
"Normally there is a tuned circuit at the input, which consists of a
coil and capacitor in parallel.   The DC flows through the coil.

At the output there either is a high-impedance magnetic headphone,
which conducts DC through its coil, or a crystal headphone with a
resistor in parallel for the DC path."

Next the DC flows into "ground":
"The use of the term ground (or earth) is so common in electrical and
electronics applications that circuits in portable electronic devices such
as cell phones and media players as well as circuits in vehicles such as
ships, aircraft, and spacecraft may be spoken of as having a "ground"
connection without any actual connection to the Earth. This is usually a
large conductor attached to one side of the power supply (such as the
"ground plane" on a printed circuit board) which serves as the common return
path for current from many different components in the circuit." From:
http://en.wikipedia.org/wiki/Ground_(electricity)

Each charged body (conductor and insulator) losts the charge (leakage) with
time.

Add the additional real ground and tell us the results.

NO NO NO NO NO!!!!
```

The DC flows in a circle inside the receiver!!!

When you see the schematic diagram of a working crystal receiver, you can make a trip trough the diode, through other components in the receiver, all conducting DC, back to the the point where you started at the diode.

This path must exist and this is where the DC flows.
When there is no such path, a DC voltage equal to the peak value of the HF voltage will develop across the diode, the diode will no longer conduct, and there is no more rectification. Hence the receiver will not work.

This is not related to "ground".   There must be HF voltage at the input of the receiver, but it is not important if it is between a monopole antenna and ground or between the poles of a dipole.

You can even make a crystal receiver with a ferrite rod as an antenna, which will operate without any ground.

The oscillatory flow of electrons is inherently not symmetric.
Always some of them jump off from the antenna end. VSWR =1 means that all
jumps off.

It should be obvious for you if you see the electrons in the wire.
For Pointing there no electrons. There are only fields around the wire.
He wrote: " Formerly a current was regarded as something traveling along a
conductor, attention being chiefly directed to the conductor, and the energy
which appeared at any part of the circuit, if considered at all, was
supposed to be conveyed thither through the conductor by the current. "

And next: "The aim of this paper is to prove that there is a general law for
the transfer of energy, according to which it moves at any point

perpendicularly to the plane containing the lines of electric force and magnetic force, and that the amount crossing unit of area per second of this plane is equal to the product of the intensities of the two forces, multiplied by the sine of the angle between them, divided by , while the direction of flow of energy is that in which a right-handed screw would move if turned round from the positive direction of the electromotive to the positive direction of the magnetic intensity".

The teachers buy it.

Before Haeviside and Pointing was " something traveling along a conductor".
What do you prefer: electrons or fields?

The path is the ground: "The use of the term ground (or earth) is so common
in electrical and
electronics applications that circuits in portable electronic devices such
as cell phones and media players as well as circuits in vehicles such as
ships, aircraft, and spacecraft may be spoken of as having a "ground"
connection without any actual connection to the Earth. This is usually a
large conductor attached to one side of the power supply "

Each voltage disappear (leakage) with the time. That before diode and that
after. The leakage is always and everywhere.
The leakage is surface and humidity dependent.
>
> You can even make a crystal receiver with a ferrite rod as an

Leakage do the work.

You keep claiming that. But you don't explain why there is no nonlinearity in the antenna. When the antenna is nonlinear, as you claim, there must be intermodulation in the antenna. But in a well constructed antenna, there is no intermodulation. So there is no unsymmetric flow of electrons.

I don't care what people have written in the 19th century. Please stop bringing that up. I am only interested in how things are explained today.

Can't you read?
Or are you even dumber than I already think?

The path is not to the ground. It is a circle inside the receiver.

Only a bad designer will design equipment that requires leakage to
operate. Of course there will be some bad schematics of crystal receivers
around, where there is no obvious DC path around the diode, and maybe
sometimes (depending on construction details) one may be able to hear
some sound, but it is NOT the way it should be done and it is NOT the
explanation of the workings of the receiver.
Except maybe to someone in 1900, who did not understand it fully.

>> You can even make a crystal receiver with a ferrite rod as an

I think leakage has done the work to your brain. Leakage from the
beer bottle, that is.

> Except maybe to someone in 1900, who did not understand it fully.

They fully understand it. They discovered the induction and the leakage (in
electrostatics).
You simply do not understand that your path is the countrpoise.

Leakage can transfer the charge from one body to the another.
The same should apply to "brain to brain".

Ah - we're back to the rectenna which is defined in Wiki thus "A simple
rectenna element consists of a dipole antenna with a diode connected across
the dipole elements".

ttfn, Ian.

Everything was discovered in XIX (for the radio):
"The electrical waves produced by the oscillations at A traveled along the

wires and were reflected at the far ends. Lodge knew that the longer spark at B3 was due to what he called the "recoil impulse" or "recoil kick" at the end of the wires where the waves were reflected.[4] At spark gap B3 both the incident wave and the reflected wave had their maximum values and were in phase. This produced a voltage twice as large as the voltage at spark gap A.
From: http://www.antiquewireless.org/otb/lodge1102.htm

Is it still true?

If yes, than you must admit that the leakage must be stronger at "recoil kick" when the voltage is doubled.
"So there is the unsymmetrical flow of electrons." Do you agree?

There is no counterpoise in this antenna.
The full-wave bridge rectifiers provide a DC path through the load
without requiring a DC path in the dipole.

Many elements are used because this antenna is supposed to operate
on microwave, and thus a single element has only a very small capture
area. You stack a lot of them to enlarge the capture area, which is
required to capture all the signals at the point of focus.

>> Except maybe to someone in 1900, who did not understand it fully.

No, the problem is that I do understand how those circuits work and
you don't. Then you fall back to what was written in 1889 instead of
looking at the design with today's knowledge.

You are too far gone to understand what the bottle has done to you.

A reflected wave along a nonterminated transmission line will result in
doubled voltage at the open end.

> If yes, than you must admit that the leakage must be stronger at "recoil
> kick" when the voltage is doubled.
> "So there is the unsymmetrical flow of electrons." Do you agree?

But here you are talking complete hogwash again. The effect you describe
above has nothing to do with leakage or unsymmetrical flow of electrons.

Here you are the simple:
http://www.ac-grenoble.fr/yre/agency/library/missions/missrep1997/online/rap-nuc2.htm

Are the dipole elements symmetrical?
It seems that one of them is a counterpoise.

Wiki says that a rectenna is "a dipole antenna with a diode connected across the dipole elements".
A dipole is a balanced, symmetrical aerial and does not have a counterpoise.
I can't be responsible for you being unable to understand what "symmetrical", "balanced" and "counterpoise" mean. I can suggest / recommend that you acquire a reference book on aerials from the ARRL or RSGB. You'd find them immensely helpful.
Regards, Ian.

Yes

> It seems that one of them is a counterpoise.

Why? I see symmetrical elements.

What you can also see here is that this is another example of what
I wrote earlier: there is a circle in the schematic starting at the
diode where you can go around with DC current and end at the same
point.
This circle is where the DC current flows, not from the elements into
the air.

But EM waves also propagate in environments where the electrons are
too far apart to kick eachother. How do you explain that?

 From the document you posted, P*G/(4*Pi*D^2) = E^2/(120*Pi)

Let G = 1, D = 3, E = 200uV then

P*1/(4*3.14*3*3) = (200e-6)^2/377 and

P/113 = 40e-9/377 so that

P = 113 * 106e-12 giving

P = 12e-9

This looks like NANOwatts to me.

It's not exactly ELMR but rather LMRS (Land Mobile Radio System) at 380-400MHz interfering with garage door openers on 315 MHz through receiver blocking (overload):
<http://en.wikipedia.org/wiki/Land_Mobile_Radio_System>
This has been a known problem for at least 8 years, yet the garage door manufactories haven't done anything in the way of improved receivers. I guess a cheap bandpass filter and some shielding would be too much for the cost concious garage door opener manufacturers.

Drivel: One of my customers was having problems with their garage door opener. They said they could easily close the door from the end of the driveway, but could not open it again from the same location. When I arrived, I found that they had an aluminum garage door, with the receiver mounted behind the door. Between the metal door and aluminium foil backed insulation in the walls and roof, the garage made an effective screen room. I moved the recevier and wire antenna to a better location, which fixed the problem.

More drivel: Many years ago, I helped setup a 30 watt Mitrek 440MHz portable repeater for an event. Since it used mechanical T/R relays, the dropout time was set rather long to minimize contact cycling. During the event, we had some traffic from drivers in the nearby parking lot about being unable to operate wireless car alarms. Oops. I turned down the TX power which allowed the alarms to operate normally. Years, they switched to VHF, which stopped blocking the car alarm receivers, and introduced triggering the car alarms.
Lesson learned: Use low tx power in parking lots.

You have been told time and time again that there is no corona in normal antenna operation.

You have been told time and time again that "oscillatory flow" is 19th century nonsense.

Why do you yet again repeat all this nonsense?

Why do you keep arguing with people who have hundreds of years of collective

experience and many with engineering and science degrees, all of whom
have told you this is nonsense?

You are an ignorant, babbling, ineducable idiot who knows absolutely
NOTHING about anything.

How many antennas have you built in your lifetime?

Why do you refuse to answer the question?

Is it because you have built zero antennas and you are trying to say all
the people that have successfully built hundreds that they are all wrong
and you don't want to admit you are an ignorant, inducable, idiot?

Why can't you obtain and read a university level textbook on anything
in any language?

Is it because you are too stupid to be able to understand the material?

Oh, I see.

You used 100 MILLIvolts (not MICROvolts) in your calculation! That's how you wound up with MILLIwatts rather than (NANOwatts).

Oh, I see.
```

You used 200 MILLIvolts (not MICROvolts) in your calculation! That's how you wound up with MILLIwatts rather than (NANOwatts).

Well, that looks right. I'll do the short version:

From Pg 29.
<http://transition.fcc.gov/Bureaus/Engineering_Technology/Documents/bulletins/oet63/oet63rev.pdf>

Assuming a 0dBi gain antenna:
Power = 0.3 FS^2
where
FS = field strength in Volts/meter
P = Watts
Plugging in:
Power = 0.3 * (200 uV/m)^2 = 0.3 * (200*10^-6 V/m)^2
Power = 0.3 * 4*10^-8 = 12*10-9 = 12 nano watts.
Argh... You're right.

However, that can't be the correct maximum power. It's much too low
to be useful.

Digging out a cheat sheet from:
<http://www.ti.com/lit/an/swra090/swra090.pdf>
CEPT (European) 1e and 1e1 are 10mw and 1mw respectively.
However, digging down to the FCC stuff on Pg 11, I find that the specs
are really in FCC 15.231(b).
<http://louise.hallikainen.org/FCC/FccRules/2012/15/231/>
and are approx 11,000 uV/meter. Grinding the numbers again...

Assuming a 0dBi gain antenna:
Power = 0.3 FS^2
where
FS = field strength in Volts/meter
P = Watts
Plugging in:
Power = 0.3 * (11000 uV/m)^2 = 0.3 * (11000*10^-6 V/m)^2
Power = 0.3 * 0.000121 = 36 milliwatts.

Thanks for catching my mistake and I'll double check the numbers
(again) when I get home from some service calls.

<snip>

#Drivel: One of my customers was having problems with their garage
#door opener. They said they could easily close the door from the end
#of the driveway, but could not open it again from the same location.
#When I arrived, I found that they had an aluminum garage door, with
#the receiver mounted behind the door. Between the metal door and
#aluminium foil backed insulation in the walls and roof, the garage
#made an effective screen room. I moved the recevier and wire antenna
#to a better location, which fixed the problem.

<snip>--

My own situation was that the remotes in the cars lost range. You could open the door if the car was practically touching the door, but not much farther back.

Using various test gear, I found an interfering signal that was just a few feet away. The remote opener screwed on the outer wall had failed in the "on" position and was closer to the receiving antenna than the openers in the cars.

The Genie engineers were quite interested in getting that failed remote in their hands to examine the problem. They were amazed that I located the problem, but it's all in the test gear.

Yes, but you are reading only part of the regulations. These are
PERIODIC radiators. Please read the whole thing and tell me how often
and for what period you can transmit.

> Thanks for catching my mistake and I'll double check the numbers
> (again) when I get home from some service calls.

Very well. Please point out the pertinent parts that allow this
(undisclosed) mode of operation.

I've seen something like that in action. The problem is in the way
the rolling code works and a rather dumb design decision in the remote
key fob:
<http://en.wikipedia.org/wiki/Rolling_code>
<http://www.atmel.com/Images/doc2600.pdf>
When you press the key fob button, some remotes just continue to spew
codes like a machine gun. I think (not sure) that my 2001 Subaru key
fob does this. The problem is that the system compares the received
code with up to 256 anticipated codes that the remote might send. The
idea is to catch up in case the key fob was accidentally pressed and
the receiver missed the transmission. However, if you send 256 codes,

the transmitter and receiver go out of sync and must be re-synchronized. I actually tried it by pressing the button 256 times and found that I could no longer unlock the car. It is my understanding that modern chips have a better algorithm that doesn't have this problem.

When your transmitter in the outer wall stuck on, it probably ran out of codes fairly quickly. After that, it was no better than a jammer.

>The Genie engineers were quite interested in getting that failed remote in
>their hands to examine the problem. They were amazed that I located the
>problem, but it's all in the test gear.

Nicely done especially since you had no idea what was causing the problem.

>Wayne
>W5GIE (exiled to W6)

I live in W6-land and methinks it's is paradise (except for the government, traffic, taxes, gas prices, etc).

>PERIODIC radiators. Please read the whole thing and tell me how often
>and for what period you can transmit.

Ummm... let's set some ground rules first. With all due respect, if your interest is learning something about FCC rules-n-regs, how the stuff works, how to make it all play together, how to grind the numbers, and where to find pieces, I'll bust my posterior to supply you with direction and/or answers. However, if your intent is make me jump through hoops, burn my time, or supply information that you could easily excavate on your own, please find someone else to play your game. I don't mind being wrong, being told I'm clueless, or doing research. I do mind wasting my time.

See the last paragraph of 15.231
<http://louise.hallikainen.org/FCC/FccRules/2012/15/231/>
   In addition, devices operated under the provisions of this
   paragraph shall be provided with a means for automatically

limiting operation so that the duration of each transmission shall not be greater than one second and the silent period between transmissions shall be at least 30 times the duration of the transmission but in no case less than 10 seconds.

The method of modulation is not specified. Whatever modulation method is chosen must comply with 15.231(b)(3)(c)

The bandwidth of the emission shall be no wider than 0.25% of the center frequency for devices operating above 70 MHz and below 900 MHz. For devices operating above 900 MHz, the emission shall be no wider than 0.5% of the center frequency. Bandwidth is determined at the points 20 dB down from the modulated carrier.

At 433MHz, that yields about 1MHz bandwidth which is adequate for most anything between on-off keying to perhaps frequency hopping spread spectrum.

>> Thanks for catching my mistake and I'll double check the numbers
>> (again) when I get home from some service calls.
>
\>Very well. Please point out the pertinent parts that allow this
>(undisclosed) mode of operation.

Sorry, but undisclosed modes are by definition undefined and therefore not codified in the FCC rules-n-regs.

This paragraph is part of paragraph (e) which allows only

260-470 1,500 to 5,000^1 150 to 500^1
^1Linear interpolations.

so that, with interpolation to 433, it works out to about 4383 uV/m.

This, then, allows .3*(4383e-6)^2 or about 5.76 microwatts for 1 second
out of every 30 seconds. Or, for 1/3 second out of every 10 seconds, but
never more frequently.

>>> Thanks for catching my mistake and I'll double check the numbers
>>> (again) when I get home from some service calls.

You're welcome (again).

Are all dipoles the  monopoles?

W5DXP wrote; "In RF conductors, electrons do oscillate but they are much too
slow to "flow".
In conductors is a lot of electrons.

EM waves are in textbooks. The electron waves propagate in plasma. There is
also a lot of electrons.
Everything what fall down on the Sun is "reworked" into plasma.

In AC electrons oscillate. In DC electrons are flowing for ages.
Where they come from?

Are you really this stupid that you would post this nonsense or are you insane?

Maybe you are just drunk all the time.

Which is it; stupid, insane, or drunk?

> But is in unnormal operation. When it (corona) is seen?

The quad beam antenna was invented by Clarence Moore to solve a corona prob=
lem encountered with a Yagi-type beam at 10k' in the Andes Mountains. Here =
is that interesting history:

http://lists.contesting.com/_towertalk/2002-11/msg00393.html

The point is that electron flow corona destroyed the Yagi-type beam but the=
re was negligible corona using the quad beam because the standing wave volt=
age maximums are much lower with the quad. Yet the two antennas radiated ap=
proximately the same magnitude of RF waves. This proves that electron flow =
is not the mechanism associated with RF radiation. It is simple to understa=
nd once one realizes that electron flow corona results in non-coherent radi=
ation while normal photonic RF radiation is coherent.

As you have been told many times but are too stupid to understand,
electromagnetic radiation can be viewed as either waves or photons.

Why are you asking again, are you stupid, drunk, or insane?

>> A rectenna is simply an antenna with something that acts as a diode at
>> it's terminals to convert the AC to DC.
>
> In AC electrons oscillate. In DC electrons are flowing for ages.
> Where they come from?

No; in AC electrons periodically change directions and in DC electrons
flow in one direction only.

An antenna is a device that converts the AC electrical energy at it's teminals into electromagnetic energy which radiates from the antenna and also converts the electromagnetic energy which antenna intercepts into AC electrical energy at it's terminals.

A diode converts AC into DC.

You are an ignorant, babbling, ineducable idiot who knows absolutely NOTHING about anything.

Well, I can't argue with the fact that they are being produced. If they really meet the FCC regulations, I have been unable to prove it. I have looked all over the FCC site under part 15 and never found an area that allows such power.

If you ever find it, I would appreciate a link to it.

> But is in unnormal operation. When it is seen?

Only when you output kilowatts of power and there is some point in
the antenna where the voltage is very high.

But a radio amateur knows that it is possible to transmit signals with
arbitrarily low power and that the range becomes smaller but it still
works all the time.  So even with very low voltages, where there is
no corona, a transmitter still transmits.

Good afternoon Szczepan.
Dipoles and monopoles are two different designs of aerial. A basic knowledge
of (I think) Latin would prove this to you.
You'd find these two types of aerial in basic/entry-level reference books
for ham
radio. Please use the links to the ARRL and RSGB book shops and get yourself
a decent book on the topic of
aerials.

Regards, Ian.

Oops and thanks (again). I keep fudging the numbers (unintentionally)
to what I think they should be, instead of what they are. Very
embarrassing.

Microwatts doesn't seem to make sense as there are products being sold
that advertise 10mw and 100mw output power levels. Obviously they are
not being certified under Part 15. However, I can't find another US
service on 433MHz that qualifies (except ham radio). FCC frequency
allocations table is of no use:
<http://ecfr.gpoaccess.gov/graphics/pdfs/er27ja12.018.pdf>
433MHz is an ISM band, but only in region 1 (Europe) and not in region
2 (US).
<http://en.wikipedia.org/wiki/ISM_band>
My guess(tm) is that the higher power 433MHz devices can only be sold
in Europe. Yet, that's not apparent on any of the sites selling
433MHz data radios.

"FCC Compliance testing Using the MICRF112"
<http://www.micrel.com/_PDF/App-Notes/an-55.pdf>
Page 9 has the calcs for a typical key fob transmitter.
36 microwatts.

>> Thanks for catching my mistake and I'll double check the numbers
>> (again) when I get home from some service calls.
>
>You're welcome again.

I'll do some more reading and checking, hopefully tonite. Paying work
comes first. My appologies (again) for my multiple screwups.

Unless I missed something, you're correct. I can't find anything in
the US rules (except Part 47 ham radio) that allows milliwatt level
operation on 433MHz. It is allowed in Europe under CEPT rules to 10mw
at 10% max duty cycle:
<http://www.ero.dk/47DA77DD-A2B7-4DD2-8288-3900A875B3F6?frames=no&>
(MS Word Document). Nothing that allows 100mw but possibly in another
foreign country.

I've only done certifications for 900MHz, 2.4GHz, and 5.7GHz, FCC 15.247 hardware. The 433MHz stuff is new to me. FCC 15.247 allows 1 watt into 6dBi.
<http://louise.hallikainen.org/FCC/FccRules/2012/15/247/>

It appears that we have both looked very hard and have come to the same
conclusion. I now wonder if the US suppliers are unaware of the region
1/region 2 thing.

I saw that. Lower left corner of page 4 says that continuous operation
is allowed. Where do they get that?

Yeah, my conclusion as well.

Here in Europe, 10mW ERP is allowed on 433 MHz.  This of course does
```

not mean that all devices have that much power. I can understand that a 13dBm transmitter device is allowed with an inefficient antenna and still result in 10mW ERP or less. 100mW seems to be a bit off the scale, who would want to waste that much power.

Unfortunately, "allowed" and "in use" are different things. It is allowed to used 10mW handy talkies on 433 for unlicensed use, but in reality those users have the wellknown Chinese devices (Wouxun etc) that output 4 watts. Or they use a 50W standard HAM mobile transceiver. Without license. On the amateur bands.

I've run into interference in a local shopping mall parking lot, which
is sufficient to almost completely block 433 MHz car keyfobs from
working. It comes from a local noodle restaurant, which uses a
wireless order-taking system... from the sound of the transmissions
over the air, I think the central node is polling the hand-held order
entry units 3-4 times per second (well in excess of the Part 15
periodic radiator limit). It's quite audible for about a city block
around the restaurant, in at least some directions.

I got a look at one of the handheld terminals, and did not see any
sort of FCC licensing or type-acceptance sticker.

Why am I not surprised? I think this could get out of hand just as the
27 MHz band did. There is a slight difference here. The military has an
interest in the 70 cm band, so this may become very interesting. Note
that near some military bases, some gadgets are becoming next to useless
already.

I still have some more reading to do, and ask a few experts. However,
offhand, methinks there's a problem.

It's there, although I had to read it several times before I found it.
<http://louise.hallikainen.org/FCC/FccRules/2012/15/231/>
See section (e):
    Intentional radiators may operate at a periodic rate exceeding
    that specified in paragraph ...

The field strength is limited to about 4500 uV/meter. There's also
some notes on the topic on Pg 14 of the TI app note:
<http://www.ti.com/lit/an/swra090/swra090.pdf>

>> is allowed. Where do they get that?
>
> It's there, although I had to read it several times before I found it.
> <http://louise.hallikainen.org/FCC/FccRules/2012/15/231/>
> See section (e):
>   Intentional radiators may operate at a periodic rate exceeding
>   that specified in paragraph ...

Yes, but continuing with paragraph (e) includes the last paragraph which
you quoted earlier:

<quote you>

See the last paragraph of 15.231
<http://louise.hallikainen.org/FCC/FccRules/2012/15/231/>
    In addition, devices operated under the provisions of this
    paragraph shall be provided with a means for automatically
    limiting operation so that the duration of each transmission
    shall not be greater than one second and the silent period
    between transmissions shall be at least 30 times the
    duration of the transmission but in no case less than 10
    seconds.

</quote you>

And this last paragraph is part of FCC paragraph (e).

There is nothing in that section which allows continuous transmission.

> The field strength is limited to about 4500 uV/meter. There's also
> some notes on the topic on Pg 14 of the TI app note:
> <http://www.ti.com/lit/an/swra090/swra090.pdf>

It is parroting paragraph (e). Nothing new nor informative there.

I'm enjoying this, Jeff. Finally, I have someone with which to kick this
around and learn something. I'd really like to get to the bottom of this
whole thing.

I'm definitely interested, and I think it's sufficiently on-topic for
this newsgroup that it's quite reasonable to continue the discussion
here.

I find it very useful since I am interested in the low (weak signal) end of 70cm.

Don't assume that because we aren't poking our noses in that there
aren't interested people out here. Please carry on where I can see it.

I've always wondered if the imported 433MHz devices were running legally.

Thanks for your inputs, guys. I probably can't do it alone, so I will be
counting on Jeff for some leadership here.

John

The crystal radio antenna has only one terminal. Before the diode is AC.
After the diode is DC.
Where electrons come from?

"Leakage current is also any current that flows when the ideal current is
zero".

Real current is not the ideal one.

There should always be a DC path around the diode, or the crystal radio
will not work.

Normally there is a tuned circuit at the input, which consists of a
coil and capacitor in parallel.   The DC flows through the coil.

At the output there either is a high-impedance magnetic headphone,
which conducts DC through its coil, or a crystal headphone with a
resistor in parallel for the DC path.

The electrons circulate around the DC path in the receiver.

No you were telling that electrons were jumping off the antenna because
of corona, which is nonsense when the transmitter is low power, and
points to an operational problem when the transmitter is high power.

The average Pole may not be stupid, but that does not mean there don't
exist very stupid Poles.

In message <e9jt08parnl5h7598qb1k15if9fo30fau4@4ax.com>, Jeff Liebermann
<jeffl@cruzio.com> writes
>

>My guess(tm) is that the higher power 433MHz devices can only be sold
>in Europe. Yet, that's not apparent on any of the sites selling
>433MHz data radios.

It's unlikely that any high power short-range devices are legally on
sale in Europe. The UK spec is 10mW erp (which is probably the norm).
<http://stakeholders.ofcom.org.uk/binaries/spectrum/spectrum-policy-area/
spectrum-management/research-guidelines-tech-info/interface-requirements/
IR_2030.pdf>
page 17.

Of course, over here, 70cm is only 430 to 440MHz, and (for various
reasons) most of the simplex activity is 432 to 434MHz. An SRD
allocation at 433MHz can cause some interesting problems - especially to
car key systems which, in the past, have often had fairly 'elementary'
and unselective receivers. It is said that great fun can be had when
you're sitting in your car in the shopping mall carpark, waiting for
your wife to emerge from the shops.

```

Father of the famous vector wrote in 1884 (before the Hertz experiment):
"The whole of the energy then enters in through the external surface of the wire, and by the general theorem the amount entering in must just account for the heat developed owing to the resistance,"

A few days ago Jimp wrote:
"An antenna is a device that converts the AC electrical energy at it's terminals into electromagnetic energy which radiates from the antenna".

So "enters in = radiates from"?
Can anybody help?
